INDEX TO VOLUME CLI.

AUTHORS.

Adams, J. F. Alleyne. A case of malignant endocarditis, 396.
Arloing and Courmont. Serum diagnosis of tuberculosis. The historical aspect of the subject. The technique for investigating the serum reaction of tuberculosis. Difficulties and sources of error. Results and conclusions, 617.
Arthur, William H. Surgery on old men, 234.

Badger, George S. C., and Cabot, Hugh. The interrelation of medicine and surgery in the treatment of gastric ulcer, 259.
Balch, F. G. Theories as to the cause of the vicious circle, 325.
Bartol, John W. Progress in thoracic disease, 296.
Beebe, Theodore C., Jr. A comparison of anesthetics. Results from chloretone, 376.
Blake, J. B. A ureteral calculus of unusual size, 463; strangulated femoral hernia, relieved by abdominal operation. Raynaud's disease; gangrene of forearm, 265.
Bonney, S. G. Remarks upon the general principles of management of pulmonary tuberculosis, 286.
Bowditch, Vincent Y. Pulmonary tuberculosis and sanatorium treatment, 588.
Bowen, John T. Report on dermatology, 216.
Brackett, E. G., Bradford, E. H., Lovett, R. W., Thorndike, Augustus, and Dane, John. Congenital dislocation of the hip. Report of orthopedic staff of the Boston Children's Hospital based upon observations on 144 cases, 85.
Brackett, E. G., Stone, J. S., and Low, H. C. Aciduria (acetonuria) associated with death after anesthesia, 2.
Bradford, E. H. Arthritis deformans, 534; metatarso-tarsal valgus or humped foot and its relation to boots, 560; treatment of lateral curvature, 479.
Bradford, E. H., Lovett, R. W., Brackett, E. G., Thorndike, Augustus, and Dane, John. Congenital dislocation of the hip. Report of orthopedic staff of the Boston Children's Hospital based upon observations on 144 cases, 85.
Brown, D. J. Malpositions of the uterus; their causes and treatment, 153.
Bullard, W. N., and Sims, F. Robertson. A case of diffuse encephalitis showing the pneumococcus, 647.
Burrage, W. L. Recent progress in gynecology, 381, 409.
Burrell, H. L., Cushing, H. W., and Stone, J. S. Report of cases from the surgical service of the Children's Hospital, Boston, Mass. Second series, 685, 717.

Cabot, Hugh. Anterior v. posterior gastro-enterostomy, 325.
Cabot, Hugh, and Badger, George S. C. The interrelation of medicine and surgery in the treatment of gastric ulcer, 259.
Cabot, Richard C. Conclusions from a series of measurements of blood pressure in fevers, before, during and after the administration of strychnia, 346; the ideal of accuracy in clinical work: its importance, its limitations, 557.
Canedy, F. J. A case of suspected homicide proved to be suicide by strychnia, 715.
Cheever, David W. The ideal doctor, 510.
Cheever, David W., Porter, C. B., and Painter, Charles F. Congenital dislocation of the hip. Report of the committee of the Boston Society for Medical Improvement, 92.
Chute, Arthur L. The pain of osteo-arthritis of the spine: its bearing on the diagnosis of urinary disease, 563.
Clark, F. C. Concerning acetanilid, 539.
Codman, E. A. Remarks on the résumé of Dr. F. B. Harrington's service for the year 1902, 74.
Coolidge, A., Jr. The extraction of foreign bodies from the bronchi, 395.
Cotton, F. J. Clinical topography of lymph nodes, 229; laryngotomy and removal of one cord for benign tumor of larynx. Operation for "dropped knuckle," 266.
Coues, W. P., and Robey, W. H., Jr. Post-operative erysipelatous dermatitis in an infant of one month; recovery, 719.
Councilman, W. T. The modern conceptions and methods of medical science, 425.
Courmont and Arloing. Serum diagnosis of tuberculosis. The historical aspect of the subject. The technique for investigating the serum reaction of tuberculosis. Difficulties and sources of error. Results and conclusions, 617.
Crothers, T. D. American Medical Society for the Study of Alcohol and Other Narcotics, 227.
Cumston, Charles Greene. Remarks on the jurisprudence of civil malpractice, based principally on the decisions rendered by the French courts, 623, 655.
Cushing, H. W. Acute appendicitis, gangrene, perforation, general peritonitis, recovery. General suppurative peritonitis, toxemia, adrenalin, infusion, recovery. Intestinal obstruction from stricture due to adenocarcinoma, resection of colon, recovery. Phlebitis of the vena cava following typhoid. Supposed tuberculous tumor of the pons cerebri. Senile gangrene of the leg, amputation of thigh, recovery. Raynaud's disease, 266.
Cushing, H. W., Burrell, H. L., and Stone, J. S. Report of cases from the surgical service of the Children's Hospital, Boston, Mass. Second series, 685, 717.
Cutler, E. G. A case of chronic leukemia. A case of subacute articular rheumatism. A case of methemoglobinemia. A case of emphysema. Chronic plethora. An unusual case of scleroderma, 72; gastric ulcer in children, 367, 402.

Dane, John, Bradford, E. H., Lovett, R. W., Brackett, E. G., and Thorndike, Augustus. Congenital dislocation of the hip. Report of orthopedic staff of the Boston Children's Hospital based upon observations on 144 cases, 85.
Darnall, William Edgar. The gynecological aspect of mental overstrain at puberty, and its influence on development, 291.
De Blois, Thomas Amory. Sub-glottic tubercular lesions of the larynx, 321.
Denny, F. P. Isolation methods and precautions in contagious disease, 711.
Donley, John E. A case of uniradicular brachial palsy affecting the fifth cervical nerve, 133; three cases of the association neurosis with remarks on its genesis, 484.
Downing, Bertha C. Mental defectives, 236.
Draper, A. D. A device for greater accuracy of dilution of Thoma-Zeiss pipettes, 684.
Dwight, Thomas. A card catalogue of anatomy, 451.

Edes, Robert T. Mind cures from the standpoint of the general practitioner, 173.
Edson, Carroll E. A meteorological study of the winter of 1903–04, 92.
Elliot, J. W. A case of intussusception. Interstitial colitis, simulating cancer of the rectum, 72.
Emerson, Francis P. Earache, or cases of early involvement of the middle ear, usually neglected, 352.
Ernst, Harold C. Animal experimentation, 89.
Evans, Thomas Horace. On "variant" infections: with report of cases, 400.

Farlow, John W. Two cases of chronic pemphigus of the mouth, 671.
Fitch, R. B. Four cases of laparotomy during typhoid fever: with recovery, 631.
Friedman, C. V. Coma following labor, 464.

Gannett, W. W. Ulceration of primary bronchus; perforation into pulmonary artery, 72.
Gifford, N. H. Experimental decapsulation of the kidneys, 37.
Goldthwait, Joel E. The differential diagnosis and treatment of the so-called rheumatoid diseases, 529.
Goodale, J. L. The ultimate results of cauterization of the lower turbinate, with therapeutic suggestions based upon histological findings, 701.
Gould, Alfred H. An improved method of end to lateral intestinal anastomosis. A new mattress stitch, 707.
Gould, A. H., and Murphy, F. T. Coagulation-time of the blood. A comparison between the Wright and the Brodie-Russell instruments, based upon six hundred observations, 45.
Guiteras, Ramon. Fourth Pan-American Medical Congress, 503.

Hall, William D., and Standish, Myles. Recent progress in ophthalmology, 490.
Hare, Henry F. Standard records of the leucocytes in normal blood for reference in clinical work, 705.
Higgins, Frank A. Report on obstetrics, 243, 270.
Hill, Hibbert Winslow. Innocent cases reported as diphtheria, 654.
Hill, Hibbert Winslow, and Slack, Francis Henry. Bacterial counts of Boston's milk supply, 708.
Hubbard, Joshua C. Case of rupture of the spleen, 443.

Jackson, Henry. Chronic joint disease, 535; disease of the myocardium, 339.
Jacobs, Henry Barton. Tuberculosis, its nature and prevention, 505.
Johnson, Frank M. The union of the teachings in cystoscopy and microscopy, 132.
Jones, Daniel Fiske. Abscess of the liver following abdominal infections, with a report of four cases, 341; a case of intraperitoneal rupture of the bladder, 515; remarks on exploratory laparotomy in cachectic subjects, 324.
Jones, Daniel Fiske, and Simmons, Channing C. Report of a case of primary carcinoma of the appendix, 566.
Joslin, Elliott P. Progress in gastro-intestinal diseases, 161, 191.
Joslin, Elliott P., Lund, F. B., and Murphy, F. T. Operations upon benign diseases of the stomach at the Boston City Hospital and Massachusetts General Hospital, 1898–1903 inclusive, 113.

Knapp, Philip Coombs. Recent progress in neurology, 99.
Knight, Frederick I. What shall we do with patients having pulmonary tuberculosis? 257.

Leland, G. A. Leucoplakia of tongue. Cicatricial stricture of pharyngeal orifice, relieved by plastic operation, 295.
Lord, Frederick T. Flies and tuberculosis, 651.
Lovett, R. W., Bradford E. H., Brackett, E. G., Thorndike, Augustus, and Dane, John. Congenital dislocation of the hip. Report of orthopedic staff of the Boston Children's Hospital based upon observations on 144 cases, 85.
Low, H. C., Brackett, E. G., and Stone, J. S. Aciduria (acetonuria) associated with death after anesthesia, 2.
Lund, F. B. Fractures of the radius in starting automobiles, 481.
Lund, F. B., Joslin, E. P., and Murphy, F. T. Operations upon benign diseases of the stomach at the Boston City Hospital and Massachusetts General Hospital, 1898–1903 inclusive, 113.

Manley, Thomas H. The mamma, its physiological purposes, 461.

Miller, Lester C. The decrease in the death-rate of consumption, 678.
Millet, Charles S. The practical application of hydrotherapeutic measures, 205.
Miner, W. W. Pulmonary congestion as a cause of sudden death, 682.
Morrill, F. Gordon. The Assouan cure, 440.
Morse, John Lovett. Rheumatoid disease in children, 537; report on pediatrics, 687.
Morse, John Lovett, and Rotch, Thomas Morgan. Report on pediatrics, 658.
Mumford, James G. Four cases of Finney's operation on stomach, 73.
Munro, John C. Operations on the stomach, with report of cases, 145, 183, 210, 239.
Murphy, Fred T. A study of amputations of the lower extremity, 33.
Murphy, Fred T., and Gould, A. H. Coagulation-time of the blood. A comparison between the Wright and the Brodie-Russell instruments, based upon six hundred observations, 45.
Murphy, Fred T., Lund, F. B., and Joslin, E. P. Operations upon benign diseases of the stomach at the Boston City Hospital and Massachusetts General Hospital, 1898–1903 inclusive, 113.
Musgrave, Percy. Examination of pleural fluids with reference to their etiology and diagnostic value, 317, 347, 377, 406.

Ogden, J. Borgen. Functional albuminuria, with a report of a case, 40: report of physiological chemistry, 542.
O'Neil, Richard Frothingham. Hematuria due to Bilharzia hematobia, with the report of a case, 453.

Page, Charles W. Mechanical restraint and seclusion of insane persons, 590.
Painter, Charles F. Types of rheumatoid disease, 538.
Painter, Charles F., Cheever, David W., and Porter, C. B. Congenital dislocation of the hip. Report of the committee of the Boston Society for Medical Improvement, 99.
Palmer, Lewis M. The tendencies of the practice of medicine as a profession and an art, 309.
Palmer, Sarah Ellen. Adeno-carcinoma of intestines involving the bladder, 47: letter from Munich, 725.
Pease, E. A. Gastro-enterostomy. After-treatment, 326.
Perkins, Jay. The diagnosis of incipient pulmonary tuberculosis, 627.
Perry, H. B. Implantations of silver filigree for cure of large ventral hernia. Report of two cases, 97.
Porter, C. A. Technique of gastro-enterostomy. Special preparation of patient for operations on the stomach, 323.
Porter, C. B., Cheever, David W., and Painter, Charles F. Congenital dislocation of the hip. Report of the committee of the Boston Society for Medical Improvement, 99.
Post, Abner. Tabes dorsalis, with surgical complications, 266.
Powers, George H., Jr. Plastic operations for resection of the nasal septum and excision of septal spurs, 513.
Pratt, Joseph H. The present status of hydrotherapy and other forms of physical therapeutics, 201.
Putnam, James J. A consideration of mental therapeutics as employed by special students of the subject, 179: the value of the physiological principle in the study of neurology, 641.

Reynolds, Edward. President's address before the American Gynecological Society, 1.
Richardson, Maurice H. On certain unavoidable calamities following surgical operations, 583.
Robey, W. H., Jr., and Coues, W. P. Post-operative erysipelatous dermatitis in an infant of one month: recovery, 719.
Rotch, Thomas Morgan, and Morse, John Lovett. Report on pediatrics, 658; report on pediatrics, 687.

Sabine, Wallace C. The physical relationship of Finsen light, Röntgen rays and radio-activity, 159.
Sajous, C. E. de M. Internal secretions, 393.
Scudder, Charles L. A gastro-enterostomy clamp, 442; spindle-cell sarcoma of foot. Amputation. Recovery. Lung metastases. Death. Autopsy, 264: the technique of resection of cecum, 511.
Scudder, Charles L. Chronic gastric ulcers. Hour-glass deformity of the stomach. Report of a case successfully operated, 676.
Sears, George G. A case of Addison's disease. A case of cancer confined to the papilla of the common bile duct, 295.
Simmons, Channing C., and Jones, Daniel Fiske. Report of a case of primary carcinoma of the appendix, 566.
Sims, F. Robertson, and Bullard, W. N. A case of diffuse encephalitis, showing the pneumococcus, 647.
Slack, Francis Henry, and Hill, Hibbert Winslow. Bacterial counts of Boston's milk supply, 708.
Smith, D. D. Pericemental abscess, 372.
Smith, Howard H., and White, Franklin W. Heart complications in diphtheria. A clinical study of 946 cases, 433.
Smith, Theobald. Leprosy, 675.
Standish, Myles, and Hall, William D. Recent progress in ophthalmology, 490.
Stedman, Henry R. A case of moral insanity with repeated homicides and incendiarism and late development of delusions, 57; report on mental diseases, 567, 601.
Stimson, F. J. The Assouan cure. From a layman's point of view, 433.
Stone, J. S. Subperiosteal fractures of the humerus in children, 157.
Stone, J. S., Brackett, E. G., and Low, H. C. Aciduria (acetonuria) associated with death after anesthesia, 2.
Stone, J. S., Burrell, H. L., and Cushing, H. W. Report of cases from the surgical service of the Children's Hospital, Boston, Mass. Second series, 685, 717.

Tallant, Alice Weld. Some observations on the occurrence of Broadbent's sign, 457.
Taylor, E. W. Pott's disease. Treatment at a late stage. Remarks on the pathological anatomy, 595: sacral spina bifida, with reference to the skin representation of sacral nerve roots, 208.
Taylor, J. Madison. Dr. Sajous on "internal secretions," 365.
Thorndike, Augustus, Bradford, E. H., Lovett, R. W., Brackett, E. G., and Dane, John. Congenital dislocation of the hip. Report of orthopedic staff of the Boston Children's Hospital based upon observations on 144 cases, 85.
Towle, Harvey F. Clinical report from the ward for skin diseases at the Massachusetts General Hospital, 629.
Townsend, C. W. Vulvo-vaginitis in children. A method for obtaining sputa for bacteriological examination in infants and young children. Mouth temperature and rectal temperature, 75.

Vickery, H. F. Chronic joint disease at the Massachusetts General Hospital, 536.

Watson, Francis S. Clinical lecture on urethral stricture delivered at the Boston City Hospital to fourth year Harvard medical students, 611: obstructive renal retention and anuria, and its treatment, 281: penetrating bullet wounds of right lung, liver and stomach, superficial wound of scalp. Laparotomy. Purse-string suture of stomach wound, and closure of wound of liver by interrupted sutures. Recovery, 462.
Webber, S. G. Cases illustrative of syphilis of the nervous system, 486.
White, Franklin W., and Smith, Howard H. Heart complications in diphtheria. A clinical study of 946 cases, 433.
Whitney, Charles M. The etiology and modern methods of treatment of chronic urethritis, 66.
Withington, Charles F. A case of malignant endocarditis with recovery, 99.

SUBJECTS.

Addresses. The ideal of accuracy in clinical work: its importance, its limitations, Cabot, Richard C., 537; the modern conceptions and methods of medical science, Councilman, W. T., 425: animal experimentation, Ernst, Harold C., 29: tuberculosis, its nature and prevention, Jacobs, Henry Barton, 505: the tendencies of the practice of medicine as a profession and an art, Palmer, Lewis M., 309: the value of the physiological principle in the study of neurology, Putnam, James Jackson, 641: president's address before the American gynecological society, Reynolds, Edward, 1.
Anesthetics. A comparison of anesthetics. Results from chloretone, Beebe, Theodore C., Jr., 376: aciduria (acetonuria) associated with death after anesthesia, Brackett, E. G., Stone, J. S., and Low, H. C., 2.

Bilharzia Hematobia. Hematuria due to Bilharzia hematobia, with the report of a case, O'Neil, Richard Frothingham, 453.
Blood. Conclusions from a series of measurements of blood pressure in fevers, before, during and after the administration of strychnia, Cabot, Richard C., 346: coagulation-time of the blood. A comparison between the Wright and Brodie-Russell instruments, based upon six hundred observations, Gould, A. H., and Murphy, F. T., 45: standard records of the leucocytes in normal blood for reference in clinical work, Hewes, Henry F., 705.
Blood Pressure. Conclusions from a series of measurements of blood pressure in fevers, before, during and after the administration of strychnia, Cabot, Richard C., 346.
Books Reviewed. Allen, Charles Warrenne, radiotherapy, phototherapy and high-frequency currents, 498; Bailey, Frederick R., a textbook of histology, 549: Bartley, Elias H., manual of physiological and clinical chemistry, 575: Bastian, H. Charlton, studies in heteromorphosis, 50: Beebe, S. P., and Buxton, B. H., outlines of physiological chemistry, 720: Bickham, Warren Stone, a textbook of operative surgery, covering the surgical anatomy and operative technique involved in the operations of general surgery, 603: Bocciardo, A. D., elettricità medica, 447: Böhm, A. A., and von Davidoff, M., a textbook of histology, including microscopic technic, 549: Boston, L. Napoleon, a textbook of clinical diagnosis. By laboratory methods for use of students, practitioners and laboratory workers, 605: Burrell, Herbert L., case teaching in surgery, 663: Busch, Frederick C., Kirkes' handbook of physiology, 575: Cabot, Richard C., a guide to the clinical examination of the blood for diagnostic purposes, 223: Casper, Leopold, and Richter, Paul Frederick, functional diagnosis of kidney disease with especial reference to renal surgery, 549: Cattell, Henry W., post-mortem pathology. A manual of post-mortem examinations and the interpretations to be drawn therefrom. A practical treatise for students and practitioners, 360: Cohen, Solomon Solis, a system of physiologic therapeutics. A practical exposition of the methods, other than drug-giving, useful for the prevention of disease and in the treatment of the sick, 388: Coolidge, Emelyn Lincoln, the mother's manual. A month by month guide to young mothers, 359: Cornet, G., American edition of Nothnagel's practice. Tuberculosis and acute general miliary tuberculosis, 472: Dana, Charles L., textbook of nervous diseases and psychiatry, 663: Davis, Edward P., obstetrics and gynecologic nursing, 274: Davison, Alvin, mammalian anatomy, with special reference to the cat, 22: Dudley, E. C., a treatise on the principles and practice of gynecology, 471: Dudley, Emilius C., and Healy, William, gynecology. Vol. VI of the practical medicine series of year books, 106: Dunham, Edward K., a textbook on normal histology for the use of students and practitioners of medicine, 549: Dwight, Edwin Welles, the medical epitome series. Toxicology, 550: Fenwick, E. Hurry, the value of ureteric meatoscopy in obscure diseases of the kidney, 521: Flick, Lawrence F., consumption a curable and preventable disease, 301: Gerrard, Percy Netterville, beriberi, its symptoms and symptomatic treatment, 663: Gerrard, Percy Netterville, beri-beri, its symptoms and symptomatic treatment: being extracts from "an essay on beri-beri," 663: Gowers, William R., lectures on diseases of the nervous system, 106: Halliburton, W. D., Kirkes' handbook of physiology, 575: Halliburton, W. D., the essentials of clinical physiology, 663: Hare, Hobart Amory, Hare's practical therapeutics: a textbook of practical therapeutics: with especial reference to the application of remedial measures to disease and their employment upon a rational

basis, 633; Head, Gustavus P., the practical medicine series of year books. Vol. II, general surgery, 359; Holland, J. W., the urine and clinical chemistry of the gastric contents, the common poisons and milk, 662; Illoway, H., the summer diarrheas of infants. Their etiology, pathology and treatment, 360; international medical annual: a year book of treatment and practitioners' index, 633; Jacobi, portfolio of dermochromes, 472; Janeway, Theodore C., the clinical study of blood pressure. A guide to the use of the sphygmomanometer in medical, surgical and obstetrical practice, 720; Kraepelin, Emil, lectures on clinical psychiatry, 574; Kyle, D. Stomach. The interrelation of medicine and surgery in the treatment of gastric ulcer, Badger, George S. C., and Cabot, Hugh, 259; anterior *v.* posterior gastro-enterostomy, Cabot, Hugh, 325; progress in gastro-intestinal diseases, Joslin, E. P., 161, 191; operations upon benign diseases of the stomach at the Boston City Hospital and Massachusetts General Hospital, 1898–1903 inclusive, Joslin, Elliott P., Lund, F. B., and Murphy, F. T., 113; four cases of Finney's operation on stomach, Mumford, James G., 73; operations on the stomach, with report of cases, Munro, John C., 145, 183, 210, 239; gastro-enterostomy — after-treatment, Pease, E. A., 326; technique of gastro-enterostomy. Special preparation of patient for operations on the stomach, Porter, C. A., 323; a gastro-enterostomy clamp, 442; chronic gastric ulcers. Hour-glass deformity of the stomach. Report of a case successfully operated, Scudder, Charles L., 676; penetrating bullet wounds of right lung, liver and stomach, superficial wound of scalp. Laparotomy. Purse-string suture of stomach wound, and closure of wound of liver by interrupted sutures. Recovery, Watson, Francis S., 462.

Therapeutics. Concerning acetanilid, Clark, F. C., 539; mind cures from the standpoint of the general practitioner, Edes, Robert T., 173; the practical application of hydrotherapeutic measures, Millet, Charles S., 205; the Assouan cure, Morrill, F. Gordon, 440; the present status of hydrotherapy and other forms of physical therapeutics, Pratt, Joseph H., 201; a consideration of mental therapeutics as employed by special students of the subject, Putnam, James J., 179.

Tuberculosis. Serum diagnosis of tuberculosis. The historical aspect of the subject. The technique for investigating the serum reaction of tuberculosis. Difficulties and sources of error. Results and conclusions, Arloing and Courmont, 617; remarks upon the general principles of management of pulmonary tuberculosis, Bonney, S. G., 286; pulmonary tuberculosis and sanatorium treatment, Bowditch, Vincent Y., 588; supposed tuberculous tumor of pons cerebri, Cushing, H. W., 266; subglottic tubercular lesions of the larynx, De Blois, Thomas Amory, 321; tuberculosis, its nature and prevention, Jacobs, Henry Barton, 505; what shall we do with patients having pulmonary tuberculosis? Knight, Frederick I., 257; flies and tuberculosis, Lord, Frederick T., 651; the diagnosis of incipient pulmonary tuberculosis, Perkins, Jay, 627; report of cases from the surgical service of the Children's Hospital, Boston, Mass. Second series, Burrell, H. L., Cushing, H. W., and Stone, J. S., 685; the decrease in the death-rate of consumption, Miller, Lester C., 678.

Typhoid Fever. Phlebitis of the vena cava following typhoid, Cushing, H. W., 266; four cases of laparotomy during typhoid fever: with recovery, Fitch, R. R., 631.

Urethritis. Clinical lecture on urethral stricture delivered at the Boston City Hospital to fourth year Harvard medical students, Watson, Francis S., 611; the etiology and modern methods of treatment of chronic urethritis, Whitney, Charles M., 66.

Address.

PRESIDENT'S ADDRESS BEFORE THE AMERICAN GYNECOLOGICAL SOCIETY.*

BY EDWARD REYNOLDS, M.D., BOSTON.

Fellows of the American Gynecological Society:

You will all remember that when Lincoln was asked to speak at the dedication of the national cemetery on the battlefield of Gettysburg he embodied in his address the now familiar words, "The world will little note, nor long remember, what we say here, but it can never forget what they did here." The American Gynecological Society owes its pre-eminence along its chosen line less to the words than to the prolonged and daily labor of the eminent men who have composed it in the past, and must owe its future to the life-work of the equally able men who are to fill its membership in the coming years. He who has been elevated, however unworthily, to its presidency must necessarily feel, as he begins his presidential address, that what he has to say here will be of little note nor long remembered; and as he looks back along the line of his distinguished predecessors may well question whether he too can worthily occupy his allotted portion of your too scanty time. Yet he can but feel that so time-honored a custom as the delivery of a presidential address must have a well-established reason for its existence, and, as he searches his thoughts for material that may be worthy of the occasion, may well wonder what that reason is.

In the commercial world there is a custom which is universally conceded to be essential to prosperity, of devoting a periodic portion of its working time to the process known as "taking stock," of pausing in its labors to estimate the present, to review the past, and from its failures or successes to forecast the future. Such, it seems to me, should be the purpose of our presidential address.

The president of the society may not be, indeed, must often feel himself far from the wisest or most devoted of its members, yet his fulfillment during the year of the duties of the office must necessarily have led him to give thought and consideration to many matters affecting the welfare of the society, which, but for those duties, would hardly have attracted his attention. It is therefore fitting that he should have an opportunity of making to the society such suggestions for the better guidance of its business as his work may have led him to conceive.

Among the many and striking changes in the habits of professional life which have occurred within the memory of the elder of you, indeed, among those which we younger men have noted, even in the last two decades, we must be struck with the decreasing prominence of the medical society. With the increasing complexity of modern life in general the annual meeting has become far less the great event of the year than it was to our fathers. With the enormous and from many points of view regrettable increase in the number of medical publications, with the increasing prevalence of the habit of having everything come to the office desk, to be abstracted and prepared by assistants before it reaches the eyes of the chief, the actual hearing of the papers presented at any society has become of less pressing importance to all of us. There has been of late years a notable tendency towards consolidation of local societies and a consequent decrease in the number of meetings of which one is notified, or which he is expected to attend, and although geographical circumstances have as yet delayed the appearance of this tendency among national societies the signs of it are in the air. Few societies still persist which do not worthily fill some special niche. Only such are likely to continue to exist in the future, and we must keep an eye upon our laurels.

The main *raison d'être* of such a society as this must, it seems to me, lie in the opportunity which it, and it only, presents to each of us of knowing and appreciating the abilities of a set of picked men coming from sections distant to us, of knowing and appreciating both the men and their work as we could not without these meetings, and to this end the written paper presented by one man is of far less value than the spoken and more informal debate which calls out the energies and develops the peculiarities of knowledge and ability, even of the foibles and weaknesses, of many men. It is in the discussion, rather than by the written paper, that we learn to know and appreciate each other.

Our program is always a crowded one, and it is desirable that it should be so, that it should guide the discussion through many phases of gynecological work, and set forth the ideas of many men; but to insure full discussion of a varied and interesting list of papers demands, year by year, an increasing accuracy of organization. The twenty minutes' time which we now allot to each reader is already longer than is given by most scientific societies, and I think we have all noted that but few fellows succeed in commanding the undivided attention of their audience for the whole of even this period of time. Yet we must not forget that the papers are afterwards to reach a larger audience through publication, and that it is difficult, if not impossible, to worthily present an important topic within the limit which can be delivered in even a longer time. In this dilemma we may well turn to the collective experience of other societies, to the various expedients which one or another of them have adopted to meet their difficulties, and to a consideration of how such expedients as have been there found useful may be adapted to our peculiar needs.

The use of the printed abstract published beforehand has of late become increasingly prominent in many of our sister societies, and in

* Read at the 29th annual meeting, Boston, May, 1904.

the British Medical Association, the meetings of which have the reputation of being among the most successful and interesting of all societies, this use of the abstract has reached its highest terms, as yet. It is seldom wise to adopt wholesale the regulations of other organizations. It is usually better to let changes follow a more gradual and natural evolution under the needs of the individual assembly, but the methods of the English association may well be worth a passing consideration from you, and especially from those of you who must in their turn guide the destinies of our society.

A fellow of the British Medical Association who desires to present a paper at one of its meetings must put it in the hands of the secretary, complete and in the form in which he desires its publication, a number of weeks before the meeting, and the communication may be of any length he chooses. A paid secretary, a qualified and experienced medical author, then abstracts each paper into the form and length which he considers best fitted for spoken delivery. This official then reads the abstracts to the society, as they are called from the program. Such a reading inaugurates each discussion, and the member whose ideas have been thus succinctly set before his associates takes part in the discussion and closes it. It is said that their experience shows that the ideas of the individual member are by his method better and more intelligibly presented to the society than if he had read to them his complete paper. The time of the society is economized, full debate is encouraged, and at the same time the member has the advantage of publishing to the world a paper in which his points are set forth at the fullest length and without time limitation. Such a method is perhaps too far advanced for our present needs or possibilities, yet it has many advantages, and has seemed to me worth calling to your attention as one towards which we might well advance. A similar method has been adopted by common consent in the Association of American Physicians, and is spoken of with much enthusiasm by the members of that society. Would it not be wise for us to give this method, or a modification of it, a year's trial?

We must not underestimate the value of the other, the social, side of our meetings; but, indeed, none of us are likely to forget or undervalue the warm friendships and charming half hours which accrue to all of us from our membership in the society.

In limiting the remainder of my address to the expression of my opinion that in the now crowded state of our programs it would be better for the society that the conventional length of the presidential address should be curtailed, I feel that if I am right in this opinion, it will be evidenced by the conduct of my successors in this honored office. If their course should show me wrong, may I hope that you will at least believe that I have not been actuated by any unworthy desire to curtail my own labors, but rather that I have been willing to risk the possibility of incurring such odium for what I believe to be the advantage of the society.

In conclusion, may I take this opportunity of expressing to each and all of you my thanks for the kindly personal feeling which must have actuated you when you elected me to your presidency, for which, and for the many personal pleasures which I have enjoyed in this society, I am, and must always gladly remain, your willing debtor.

ACIDURIA (ACETONURIA) ASSOCIATED WITH DEATH AFTER ANESTHESIA.

BY E. G. BRACKETT, M.D., J. S. STONE, M.D., H. C. LOW, M.D., BOSTON.

Presented for the Staff of the Children's Hospital, Boston.

THE attention of the surgical staff of the Children's Hospital has been challenged by the following facts:

On the 6th of October, a boy of ten years and a girl of eight years entered the hospital. Each had an extensive infantile paralysis of long standing. Otherwise each was well at the time of entrance. The boy remained perfectly well until four days after his entrance to the hospital, when he began to vomit persistently. The vomitus was watery, of light green color. Up to that time the bowels had moved freely. The abdomen was soft, but not distended. When the vomiting began, the pulse became very weak and increased in rate from 95 to 150. The temperature which had been normal rose gradually to 105.8. The child became unconscious, the condition gradually failed until death, twenty hours after the onset of the vomiting.

The girl had, on several occasions during the preceding year, had attacks of persistent vomiting, associated with collapse and rapid pulse. The child seemed delicate, but of sound health, except for the infantile paralysis. Four days after entrance, three tendon transplantations were done under ether anesthesia. The operations consumed one and one-half hours in time, but were insignificant in severity, and no blood was lost. The child took ether rather poorly, and during the operation had a rapid pulse. She vomited in coming out from the ether, as is usual, but seemed comfortable and in fair condition twelve hours later. She then suddenly began to vomit persistently. The pulse became very rapid, about 190, and of poor quality; the temperature gradually rose to 106. The vomiting lasted about thirty hours. The child then gradually sank into a delirious stupor and died forty-two hours after the operation, thirty hours after the vomiting began.

Six weeks later, on Nov. 16, a girl of five and a half years, also with an extensive infantile paralysis, entered the hospital. On the day after entrance, under ether anesthesia, the fasciæ on the upper outer part of both thighs were cut by open incision. The operation was short and very little ether was used. The child recovered well from the ether and was comfortable up to thirteen hours after operation. She then began to vomit. During the night she was very restless and noisy, sleeping only three hours during the night following the operation. Twenty-four hours after the operation, the circulation became very poor. In spite of the fact that there was no obstruction to respiration the color became livid blue, the face grew

cyanotic, the extremities were cold, the pulse weak and rapid, the expression was anxious. Thirty hours after operation the child became delirious. On the second morning after operation, the child became more dull and apathetic, until she gradually passed into a condition of coma, and died forty-eight hours after operation.

In this case the peculiar, sweet, chloroform-like odor of the breath led to the examination of the urine for acetone and diacetic acid, both of which were found to be present. No test for acetone was made in the two cases entering on the 6th of October; in one of them, however, the characteristic odor of the breath was remembered very distinctly.

On Dec. 17, two more patients, each with extensive infantile paralysis of long standing, entered the hospital. They were girls, aged six and eight years. One child began to vomit six hours after entrance; the other fifteen hours after entrance. Both became markedly dull and stupid. In each case the odor of the breath was characteristic, each had acetone and diacetic acid in the urine. Both fortunately recovered.

On Dec. 26, a girl four years old entered the hospital. For six days before she had been vomiting at frequent intervals. There had been no movement of the bowels since the vomiting began. The odor of acetone in the breath was very strong, acetone was present in the urine. An intestinal obstruction by Meckel's diverticulum was found and relieved by operation. The child died twenty-six hours later, having gradually become unconscious. In this case the presence of acetone seems probably to have been incidental to the intestinal obstruction; perhaps undue importance was attached to it because of the preceding six cases, in some of which acetone had been found. Operation was delayed a little because it was uncertain at first that obstruction existed.

After this, the sweet odor of the breath was noticed in a number of patients after operation. In these the urine was examined for acetone, which was found to be present. In most of them vomiting occurred, and some showed marked prostration, but in only the following case, however, were the symptoms alarming:

A girl of four, rather delicate and nervous, suffering from double congenital dislocation of the hip, had been operated upon by the Lorenz method five months before. Reduction of the hip had been easily effected, and the limb placed in the frog position with the usual spica bandage. Both hips were not reduced at once, as the child did not seem strong. The patient recovered from the operation without trouble and was returned home after a few days. The child was unable to learn to walk about, and returned to the hospital five months later in rather a poorer condition than on her first entrance, though her condition was not at all alarming. The child was quite nervous and frightened at her second operation. In manipulating the reduced hip, and changing it from the first to the second position, requiring but little force, as well as in the manipulative reduction on the unreduced hip requiring more force (though much less than is required in many cases), a separation of the epiphyses at the lower ends of both femora occurred, which indicated that the child was less strong than at the first operation. A double plaster spica was applied, and the child returned to the ward, the operation having been a short one, not requiring more than half an hour in all. The child recovered from the anesthesia well. There was a little nausea, there was absolutely nothing in any way unusual or alarming in the condition until six o'clock on the morning after operation, an interval of twenty hours. The pulse then grew suddenly weak and rapid, the color became poor, but after a hypodermic injection of strychnine she improved. The child seemed a little dull, there was no vomiting, the breath was sweet. Acetone was found in the urine. Three hours later there was another sudden collapse. During the day the child grew rapidly worse, she sank into a restless, unconscious condition, the lips became very blue. Except for rallying somewhat during the evening, the child gradually failed, until she died forty-two hours after the operation.

These cases present certain features in common: Vomiting associated with collapse; a very weak and rapid pulse; an absence of fever until just before death; cyanosis, in the fatal cases, causing extreme dyspnea; apathy and stupor, alternating with periods of restlessness at first, but in the fatal cases gradually deepening into coma and death; and the presence of acetone in the breath and urine.

Excluding the case of intestinal obstruction, there remain 6 cases in which the symptoms came on without operation. In three of these cases the symptoms came on the day after entrance, and in one two days after. In one case the symptoms came on after the child had been in the ward for four weeks and was up and about. In the sixth case the symptoms came on four days after entrance. This child died.

There are 7 cases in which the symptoms followed operation. Three of these patients died, 4 recovered. In the 4 milder cases which recovered, no symptoms at all appeared within the first twelve hours after operation. The symptoms came on between twelve and twenty-four hours afterward. In the 3 fatal cases alarming symptoms came on after about twelve hours, but in none of the cases was the recovery from the operation quite normal. The condition of the children caused anxiety, although there was no one definite symptom which could be defined as its sufficient cause.

Those children in whom the symptoms were severe were of a high strung, nervous temperament. The symptoms coming on after operation were usually more severe than those coming on without operation, although in the latter group one rapidly fatal case is included.

The first symptom to attract serious attention was, except in one case, the vomiting. The vomitus was always bile stained, becoming dark, but never bloody. In one fatal case, however, vomiting occurred but twice, each time from an obvious cause. Otherwise, the symptoms differed in no way from those in the cases in which vomiting was a prominent symptom.

In one case the symptoms seem unquestionably to have been due primarily to acute intestinal obstruction. And yet, even in this case, the presumably secondary acetonuria confused and masked the ordinary, or what might be termed the mechanical, symptoms of intestinal obstruction.

Restlessness at first was associated with the vomiting. Occasionally there was a certain amount of apathy either preceding or alternating with periods of restlessness.

In the milder cases there was a varying degree of prostration; in the severer cases marked collapse which was often repeated. The children would rally for a few hours only to fail again suddenly.

After a short time in some of the severe cases cyanosis and dyspnea became marked. None of the cases with marked cyanosis recovered. As the color changed, the restlessness was followed in some instance by delirium, but in all the fatal cases there gradually came on a stupor which became more profound, changing gradually to coma. Death in the fatal cases occurred from twelve to thirty-six hours after the onset of the symptoms, generally after about thirty hours. Death seemed to be due in some cases to a lack of oxygen. The struggle for breath seemed very striking till exhaustion came on.

Pathology. — The autopsy reports in the first two cases were made by Drs. Christian and Brinckerhoff. They were both cases of infantile paralysis with extensive muscular paralysis and degeneration of both lower limbs. In the first case there was a double intussusception of the jejunum, which was very evidently post-mortem. No important lesions were noted. In the second case no anatomical lesions were noted; no sufficient cause of death was found. There was a moderately fatty liver and large kidneys.

The other two autopsies occurred after the fact of the acetonuria had been fully appreciated. The third case was one of rather extensive infantile paralysis, dying within twenty-four hours after the comparatively simple operation of fasciotomy. The pathological interpretation of the cause of death in this case was practically negative, except for a very extensive fatty metamorphosis in the liver and less marked one in the kidneys. The fourth case was one of double congenital dislocation of the hips, which died within forty hours after operation. There was extreme fatty degeneration of the muscles of both thighs and a fatty liver and kidneys. In addition there was in this case a large number of eosinophilic cells in the spleen and the glandular epithelium of the stomach, which were only seen in small numbers in the intestine of the third case. These were in some cases phagocytic and similar to the cells which Mallory has shown in scarlet fever and acute infectious disease.

The only marked anatomical lesion which these cases showed was the extreme fatty degeneration of the liver and the muscles. This fact is more interesting when associated with the clinical knowledge that in the eight most severe of these cases there was either a paralysis or some disability resulting in the degeneration and atrophy of an extensive part of musculature.

Fatty liver is generally the result of the quality and quantity of the food and the general constitution. Diet rich in fat and carbohydrates may lead to it. These cases of paralysis in children often are the cause of an over-indulgence in sweets and an excess of milk and cod-liver oil which may induce the fatty liver. Gastro-enteritis in children, and in adults carcinoma, infectious disease, phthisis and drug poisoning are the causes of fatty liver. It will be noticed that these conditions are also associated with the increased excretion of acetone.

We can make no sharp distinction between fatty infiltration and fatty degeneration (Taylor). Pathologic accumulation of fat may occur in the liver without degeneration and without functional impairment of the cells, or it may occur with serious cellular changes. Clinical symptoms are slight if functions remain intact, even with great fat deposit. And that these children were all in apparent good health is evidence that there was not previous fatty degeneration of the liver. The microscopical examination of the liver cells in these cases shows only slight degenerative process and extensive fatty infiltration.

A physiologically fat liver may arise within a few hours after the ingestion of fat, but the extreme fatty liver due to phosphorous poisoning or chloroform similar to the liver in these cases does not develop for two or three days. So it seems evident that in these cases there was nothing in the anesthetic or the operation to produce the extreme fatty infiltration of the viscera. At least, we have proven that in animals the administration of acetone does not produce fatty liver unless it is prolonged for some time.

It is probable, however, that the fatty liver in these cases was not a sufficient cause of death, but that it was only associated, as is the acetonuria, with an acid intoxication which may, through general toxemia, or an excessive process of oxidation in the blood causing lack of oxygen, have been fatal. In clinically healthy children, such as these appeared to be, the fatty liver is rare. Wollstein in 390 autopsies in children found fatty liver in 133 cases (28%) and an extremely fatty liver in 39 cases (10%). These conditions, however, were noticed especially in cases of suppurative inflammation, pneumonia, and intestinal disease.

The adipose tissue of the body furnishes the fat in the liver. This has been proven by fattening animals for some time on mutton fat, and then producing a fatty liver by the administration of phlorizin, and observing that the acute infiltration of the liver consisted of mutton fat (Rosenfeld). In starved chickens, phosphorus does not cause fatty liver. So it may be that the disturbed metabolism of these cases is sufficient to cause an intoxication similar to that of phosphorus, and, occurring in these individuals with very extensive fatty deposits in the muscles and subcutaneous tissues, has a great store of fat to draw upon to cause the hepatic deposits. Although the presence of these primary intestinal poisons has not been shown, it is probable that they do exist and are the cause of the formation of the acetone bodies (Kraus). In phosphorus poisoning there is a marked increase of acetone excretion, due to the destruction of fat tissue, and this is probably true of acetone excretion after chloroform and other forms of narcosis (Schwarz).

The first two of these cases died in October, 1903, and the odor of the breath in them aroused the suspicion of acetonemia. Since the first of November, 425 surgical cases have been admitted to the wards of the Children's Hospital, and over

300 of them have been tested for acetonuria. Acetone has only been found present in the urine in 11 cases, and it has always been associated with other more or less severe symptoms.

The urine was tested in these cases by the standard tests for acetone and diacetic acid. Five cubic centimeters of urine, a crystal of sodium nitro-prussiate and a sufficient quantity of sodium hydrate to make it strongly alkaline were shaken up in a test-tube. The addition of glacial acetic acid to this gives a purple color to the foam if acetone is present. The urine was tested for diacetic acid by the addition of the strong aqueous solution of ferric chloride. A Burgundy red color shows its presence. This test for acetone is a modification of Legal's, and is at least more delicate than Gerhardt's, Le Nobel's or the sulphuric acid tests. Of course, this is not by any means a quantitative method, but it nevertheless allows one to distinguish between the presence of a trace and a considerable excess. A slight modification was introduced by one of the internes which made it even more delicate. A piece of bibulous paper, dipped in the foam and then dried, showed the characteristic purple color more delicately in the presence of quite small amounts of acetone. The more difficult quantitative tests were not practical in the routine of hospital work. In only one case was a quantitative test of the urine made.

The presence of acetone in the urine of ordinary cases of *diabetes* was first recognized by Petters in 1857, and soon after this Kaulisch described the clinical picture known as acetonemia. Many physiologists have demonstrated the presence of acetone normally in the urine. An excretion in the urine of 0.02 gm. per twenty-four hours is physiological; but under pathological conditions this may be enormously increased. The lungs excrete more acetone than the kidneys (Gelmüyden, Schwarz, L. Müller), but there is only a very small amount carried off in the feces.

There are various conditions, mostly associated with alimentation, in which acetonuria has been noted. First, in diabetes, especially of long duration, acetone is generally present in the urine. In starvation, inanition and the cachexia of malignant growths it is not uncommon, and with but few exceptions, it occurs in pregnancy with dead fetus. In peritonitis, where there is often auto-intoxication, and in the fevers of acute infectious diseases, sepsis and pneumonia, acetonuria occurs. In various nervous lesions and mental disease there is often a digestive disturbance which results in acetonuria. The excretion of acetone has been much increased artificially by alimentation, by drugs as phlorizin, and in chronic morphinism; in experiment by extirpation of the solar plexus or pancreas, and after general anesthesia.

Not even with the recognition of an excess of acetone excreted in the urine under these pathological conditions, do we have sufficient evidence of the existence of acetonemia. It is far from sure if acetone is really the toxic substance in the blood as Kussmaul thought; it is more probable that it is some of the various fatty acids from which acetone is obtained. Acetone may be in excess in the blood without producing marked symptoms or anatomical lesions. Considerable quantities can be exhibited with no harmful effects and very little increase in its secretion (von Jaksch, F. Müller, Kussmaul, Frerichs and Schwarz). We have injected, both intra-peritoneally and subcutaneously, large amounts into guinea pigs without causing anatomical lesions, unless the administration was prolonged for many days.

It is probable, as Naunyn says, that acetone *per se* is practically harmless; that the so-called picture of acetonemia is an acid intoxication or an acidosis due to the presence of diacetic and β-oxybutyric acids, and also probably lactic and various volatile fatty acids. At least, up to within the last two or three years the importance of acetone as a poison in the system has been overestimated. β-oxybutyric acid, the principal one of this group, is harmful only through its acid property of removing alkali from the body tissue. It may remove not only the fixed alkalis but also the bases of the proteids (Magnus-Levy) and thus destroy the efficiency of tissue very needful to life. However this may be, it is evident that the quantitative estimate of the acetone excretion is less important than the total acidity of the urine.

In one case of our series, the quantitative estimation of the acetone in the urine was made by Dr. Joslin. This was a child of eight years, dying twenty hours after the operation of fasciotomy. The total excretion of acetone for twenty-four hours was shown to be approximately 142 mgm. which is considerably more than normal. In cases of diabetes of long duration the daily excretion of acetone during the state of coma often reaches 100,000 mgm., but it may be true that the diet favors the secretion, and the accommodation of the system becomes gradually accustomed to the effects of this great formation of acetone.

Joslin has shown that the ingestion of 100 gm. of oleic acid will cause in a healthy man an excretion of over 1,700 mgm. of acetone in twenty-four hours without producing any other symptoms. He did not administer different amounts of the oleic acid to show whether the excretion of acetone was directly dependent on the amount ingested, but he did observe that those fatty acids that were only partially absorbed produced much less acetonuria. In these experiments the acetonuria was probably the direct result of fatty metabolism of the ingested fats taking place in the intestine, which, though of sudden inception and resulting in the formation of very large quantities of acetone, did not compare in its seriousness with a similar process taking place in the body fats of the liver and muscles.

The comparatively small amount of acetone excreted in one of our fatal cases shows that the quantitative estimation of the acetone excretion does not give a true index of the severity of the

condition, and that the presence of any considerable amount of acetone in the urine should be considered only as a probable sign of a more or less serious acid intoxication.

Now in these eleven cases showing acetonuria, there were only two in which diacetic acid was not found in the urine, and in one of these the test was not made for it. This is in accord with the idea that diaceturia and acetonuria cannot be separated (Lorenz). In most severe disturbances both are seen or they may alternate. This was clearly evident in case five in which the quantities of acetone and diacetic acid varied alternately from day to day. Gerhardt was the first to recognize this association of diacetic acid with acetone in the urine, which leads to the explanation of the origin of the acetone, from the acids, diacetic and β-oxybutyric.

Acetone has generally been said to have its source in the destruction of proteids, such as takes place in fevers and starvation. Though tissue destruction is conceded to be essential, it is not evident that acetone is the result of the breaking down of proteids (von Noorden, Honigmann). Acetone excretion may be diminished by a diet of proteids. Waldvogel administered to fasting men a diet of pure proteids and one of pure carbohydrates, but in neither case did acetonuria occur. Stadelmann and Minkowski showed an exception to this in the case of diabetes where, due to a sudden and complete administration of a meat diet there was a diminution of carbon dioxide in the blood, making it less alkaline, and coma and acetonuria resulted. A diet of proteids does not *increase* and a *diet* of *carbohydrates* generally *diminishes* the production of *acetone*. A reduced proteid diet causes the excretion of considerable acetone as a result of the destruction of body tissue (Schwarz). And in cases of poor nutrition we know that the fats of the body are drawn upon first. Bernert found acetone present eleven times in ninety-four cases of typhoid fever, but he says after the intestinal disturbance with the high fever had subsided, it was due to subnutrition and disappeared when the proteids were fed freely. Chemically there has never been success in producing acetone from proteid, but as it has been formed from gelatin (Blumenthal and Neuberg) it is probable that it may be obtained from proteid. It is, however, readily obtained from fats, and has been obtained from carbohydrates.

A constant excessive fat diet causes a large increase in the excretion of acetone (Waldvogel). When fats were fed to starving people acetonuria developed; but the subcutaneous injection of fat did not cause this result. So acetonuria is probably dependent on a fat metabolism generally associated with intestinal disturbance. That it can be induced artificially without intestinal disturbance is very true. In the normal person with full diet the addition of fat causes only a very slight increase of acetone excretion (Schwarz). A diet largely of fats, especially the volatile fatty acids of butter, results in acetonuria (Schwarz, Satta, Joslin). In the experiments of Joslin the ingestion of large amounts of sodium bicarbonate greatly increased the acetone excretion, but the reason for this is not known, and it is opposed to the statement of von Noorden that alkalis frequently decreased the excretion of acetone.

The formation of acetone is due to fatty metabolism with the formation of free fatty acids, and is largely dependent on a reduction of the carbohydrates and proteid diet and general sub-nutrition. In most of the pathological conditions in which acetonuria is recognized clinically there is a sub-nutrition, or an intestinal disturbance which results in a defective nutrition of the body, and it is associated with waste of body tissue. It may be the body fat or the food fat which is the source of the acetone, but the immediate cause is the disturbance of the metabolism.

The recognition of the occurrence of fatalities after narcosis, in which acetone and its allied compounds have been present in the urine, is by no means new. In 1894 Becker, from the Bonn clinic, reported three fatalities, after operation on diabetic subjects, in which the clinical conditions were quite similar to those observed in these and other isolated cases. The clinical symptoms in the three cases of Becker were so similar as to suggest some common cause, the condition noticed beginning as a slight but increasing dullness after the anesthetic, and after twenty-four to forty-eight hours the occurrence of a stupor, passing into a complete unconsciousness and coma, with a lack of autopsy findings. All clinical conditions seemed to him to point to some form of poisoning through acetone, and his experience with these led him to investigate the literature, where he found reported twelve fatalities, under like conditions. These were all associated with marked acetonuria, but were in cases known at the time, or after found out to have been, diabetic subjects. The condition of the patients before operation had not been such as to give reason for apprehension for the outcome, nor were the operations in themselves such as to give cause for alarm. It led him to formulate, from his observations, the statement that diabetic patients, who, even up to the time of operation, had shown no unusual symptoms under ordinary conditions, were, through some form of disturbance of metabolism, liable to pass from the narcosis into a stupor, and finally into a fatal coma, and that this is due to a condition which, at the time, was known as acetonuria, the term then used to indicate the manifestation of the presence of acetone in the secretions, particularly in the urine. There were no pathological findings in his cases which came to autopsy, except that in some there were lesions in the organs, similar to those found in cases of severe phosphorous poisoning. His supposition was that in some way the effect of the anesthetic was such that this condition resulted. This series was, however, collected from the

literature in which they had been reported as unusual fatalities, and they had not been so thoroughly investigated as would have been the case, had special interest been brought to bear on them. Becker's three cases of the series were distributed over a period of a number of months.

Brewer, in *Annals of Surgery*, October, 1902, reported a fatal case of acetonuria occurring after an operation for appendicitis. The case had presented nothing unusual in the condition previous to the operation to intimate an unusual result, and the operation itself offered nothing of remarkable interest. In clinical symptoms, the condition following the operation closely resembled the cases of Becker, and those of the series here reported, the acetone being detected both in the urine and breath.

In 1903 Dr. Leonard Guthrie published an article on "Fatal Effect of Chloroform in Children Suffering from a Peculiar Condition of Fatty Liver," in which he describes exactly the clinical condition fround in the cases here reported. In addition to his own, he collected a large number of cases of fatal results after chloroform, in which at autopsy there was found the same peculiar condition of fatty liver. In a number of cases the symptoms were what he called the "cerebral type," and these had so close a resemblance to the cases here under observation that a portion of his description could almost be taken as an illustration of some of those here reported. In it he says: "After recovery from the immediate effects of the chloroform, there was usually an interval of a few hours, at the end of which the child would begin to utter piercing cries at intervals, disturbing the whole building by its shrieks, grinding its teeth, tossing, struggling, and requiring constant attention lest dressings should be torn off or fractured bones displaced. The pupils were often dilated, sometimes unequally, the face being flushed or pale, with a look of wild terror and anxiety. Consciousness was sometimes lost early and never regained; sometimes there were intervals in which the child would be dull and apathetic, but would answer rationally when addressed, and usually deny being in pain. Vomiting was a marked feature in all but one case. It was copious, frequent and persistent, and the vomited matter sooner or later almost exactly resembled the dregs of beef-tea. In one case it was described as 'bloody,' and in another as 'coffee-ground.' Headache seemed to be absent in all cases. Pyrexia, was not a marked feature, but in some instances it rose to 104° or more. The screaming at length subsided, perhaps lulled by the morphia and other sedatives given, the vomiting became less frequent, unconsciousness led to coma, and the respiration and the pulse gradually failed, the latter becoming often imperceptible before breathing ceased. In some the vomiting and the restlessness continued almost till the end, and death occurred, with suddenness, from heart failure." In his cases the urine was examined and note made of albumin. It was reported as never suppressed, but no mention was made of the presence of acetone or its allied compounds, or of any attempt to find it. He considers at length the probable causes of the condition, among them fat embolism and toxemic poisoning. The question of carbolic acid poisoning was considered, but this cause was found to be impossible. These cases seem to have particular interest, inasmuch as they so closely resemble, clinically, this series here reported, and also that in the pathological findings they so closely resemble two of this series. In others of his, as in this series, also, there was no pathological condition found. All of his reported cases occurred after a narcosis by chloroform, but it must be remembered that this was the agent used by him.

The conclusions which were given by Guthrie as to the cause of death in his cases were:

(1) In all but two cases due to auto-intoxication.

(2) Fatty condition of the liver, and therefore functional disturbance of that organ resulted before operation.

(3) Chloroform and operation shock combined aggravated the condition already present, and led to the formation of toxic alkaloids which the kidneys were unable to eliminate.

Guthrie, in support of the theory that it was due to fatty infiltration of the liver, quotes results by a number of men who experimented upon the effect of chloroform on animals for a greater or less period. These researches appeared to prove that long continued administration of chloroform produced fatty changes in body in general, and in the liver particularly. It was also found that the fat which appeared in the organs a few hours after the inhalation of chloroform did not disappear for several days.

With the exception of Becker's three cases which occurred in diabetics, and Brewer's isolated case, no mention is made of the seriousness of this condition, independent of its association with diabetes, but the cases were reported as being of interest, as they were fatalities after operation, under conditions which had given no cause for alarm. The phenomenon of acid auto-intoxication had then been thoroughly recognized, other than in its association with diabetes. The condition had been studied by von Jacksch, Lorenz, Baginsky and others. Baginsky, in 1888, from a thorough study of the subject, reported that acetone is frequently present in fever patients, the amount corresponding to the height of the fever; that it also came from disturbances of the metabolism, and could be induced by the cutting off of some forms of nourishment, as shown both in experiments and bedside observations.

Its occurrence after an anesthetic, and in individuals in whom there had been, up to the time of the operation, no unfavorable symptoms, although diabetic, led Becker to investigate as to whether this might have resulted from the use of the anesthetic, and whether the kind of anesthetic made a difference in the production of acetone, and he made between fourteen and

fifteen hundred observations, with narcosis by different agents, with reference to its effect in producing acetone in the urine. It was shown by these, that there usually existed, after a narcosis, for a longer or shorter time, and in healthy people, a distinct amount of acetone in the urine. This occurred independently of the form of anesthetic used, although ether being the usual form of anesthetic used in the Bonn clinic, the larger number of observations were made with this agent. It was also found that acetonuria appeared without being influenced by the length of the narcosis, the kind of disease, or operation, whether bloody or bloodless, or by age in the adult person, or sex. It was found, however, that children were far more susceptible in this respect; that in children, a larger number of cases of acetonuria appeared, and the amount of acetone was greater. The average duration was from two to three days. In some cases, however, it did not disappear until the eighth or ninth day.

Lorenz, in 1890, from his observations, was inclined to attribute it to gastro-intestinal disturbance, and recognized the different forms of allied intoxications. He also pointed out the fact that it was found in those forms of gastro-intestinal disturbance which were secondary to a nervous affection, but also showed that the amount of acetone was much less when the disturbance was of nervous origin. That it could be caused by intense nervous disturbance, as fright, was shown by the well known experiment, in thrusting a dog from a window at a high altitude, as if to throw him out, and the presence of acetone demonstrated in the urine after the conclusion of the experiment.

ETIOLOGY.

The question at once arises as to the cause of the condition in the cases here reported. It is obvious that something incident to entering the hospital induced the condition in some cases, while in other more serious cases it was induced by the operation or something incident to it, and yet it is plain that there must be some deeper underlying cause or causes. A number of conditions are suggestive as having an etiological bearing, and are to be considered.

In such a series of cases the first thought is that the conditions might have resulted from anesthesia, or that they were in some way the remote results of the anesthesia. In analyzing the cases, however, we find that in one of the fatal cases and five of the milder cases the symptoms came on without operation or even anesthesia. One of the fatal cases had taken ether and been operated upon several months before without any ill effects whatever. In one case ether had been given several years before without any ill effect, and ether was given again a few days after the acetone had disappeared from the urine without any ill effect and without any reappearance of the acetone.

It seems fair to conclude, then, that anesthetization alone does not bring on the condition, or at least in a serious form.

Operative interference and operative shock cannot be regarded as the underlying cause, as is evident from the fact just stated, that in five milder and one fatal case the condition came on without operation. Furthermore, in none of these cases were the operations severe. None showed the ordinary symptoms of shock. None lost much blood, and in none was there any extensive injury of the tissues.

Ptomaine poisoning. — The question will be asked, Is not this condition one of ptomaine poisoning? The sudden onset, the nature and the severity of the symptoms, certainly suggest it, but in no case was there any diarrhea, which is scarcely ever absent in ptomaine poisoning if the patient lives long enough. There was no material rise of temperature except in the fatal cases soon before death. In one case the vomiting was slight, though otherwise the symptoms corresponded exactly to those in the other fatal cases. Furthermore, other children in the same ward at the same time and eating the same food have shown no symptoms to suggest ptomaine poisoning. These facts seem to bar out poisoning from this source.

Homesickness is suggested as a cause of the symptoms. The fact that the condition appeared usually about twelve hours after operation, no matter how long the child had been in the hospital before, would not necessarily militate against this suggestion. One patient, however, a boy with acute hip disease, four weeks after entering the hospital, while up and about the ward, was taken sick with vomiting and marked collapse. The vomiting lasted but one day, and acetone persisted for three or four days. In this case homesickness certainly was not a factor. The condition occurred also in other children who had been in the hospital before, who were old enough to know what they had been through, what they had to expect and who seemed absolutely happy. In one of the milder cases, however, a child who spoke no English and who cried constantly really seemed to bring on the condition.

Fright has been suggested as a possible cause. Two children had been in the hospital and knew what they were to expect. In some of the cases dread or homesickness or both did exist, but not to any greater degree than with many other children. The acute fright sometimes incident to taking ether did not seem to be more prominent in any of the cases than in many other children, though in the last fatal case it was quite noticeable.

One condition existing in the hospital at the time of the occurrence of these cases, though fortunately since removed, should be mentioned. Owing to the increased demands of the operative work at the hospital, the recovery ward for children after operation was taken as a service room. It had been the practice to return the patients to the wards immediately after operation. The children in the wards were necessarily

witnesses of the recovery from the intoxication of anesthesia with the noise and incoherent exaggeration of suffering. It is manifest that such a condition of affairs was calculated to increase the nervousness and anxiety of a nervous child and may have served as a contributing cause to the alarming symptoms under consideration.

The confinement of the hospital may possibly be regarded as a factor. Yet it seems that four days' confinement could not possibly have brought on a fatal condition, and it seems unlikely that the conditions would, if caused by confinement, come on after four weeks' stay, while the child was up and walking about the wards.

Change of food.— One very important factor suggests itself, especially in view of what is known in regard to the appearance of acetone in the urine after fasting, especially after cutting off of carbohydrate food. The change in diet on entering the hospital or the loss of appetite incident to it or the starvation and thirst incident to the taking of ether are factors present in every case except one, that of the child in whom the condition developed after four weeks' stay in the hospital. On the other hand it seems inconceivable that symptoms sufficient to cause death should come on so soon as a result of change or diminution in the amount of food, taken except in the presence of some other underlying conditions. In these cases the after effect of ether, the shock, or even the change in conditions and diet may have been sufficient to cause an intestinal disorder with disturbance of metabolism which set free from the excess of fats stored in the liver, muscles and subcutaneous tissues various fatty acids which caused the serious symptoms and were partly changed to acetone and so eliminated.

In looking over the cases one very striking fact appears. Barring out the fatal case of intestinal obstruction, there remain four fatal cases. Three of these had very extensive atrophy of the muscles of the lower extremities resulting from long standing infantile paralysis; the fourth had marked muscular atrophy, the result of confinement of one lower extremity in a plaster of Paris spica bandage for several months. Of the nine cases which recovered two had extensive infantile paralysis, with its consequent muscular atrophy; one had muscular atrophy; one had very acute hip disease associated with marked atrophy of the limb. Thus all the fatal cases and four of the nine cases which recovered had marked and extensive muscular atrophy. It seems a little unreasonable to maintain that two of the remaining five cases had muscular atrophy resulting from rickets, for the consequences of which they were admitted.

As Waldvogel says, acetone is certainly a production of fat, and it appears in abnormal amounts in the urine when the demand for energy must be met by tissue waste and the breaking down of body fats, and when there are large amounts of fat in the intestine. There was not in these cases any excess of fat ingested, but the store of body fat was in nearly all of them exceptionally great, and though they were apparently well, it is evident that most of them were afflicted with some chronic wasting trouble, which made them more susceptible to a slight change of conditions, or this demand for energy which could only be met by breaking up the store of fats into nutritious and at the same time toxic products.

At least, it remains for experiment to prove whether an extensive fatty degeneration of the muscles may not take away the metabolic efficiency of so much muscle tissue, and leave a deposit of fat to co-operate with the fatty liver in the cause of the serious results associated with acetonuria.

There are many conditions in these cases which present questions of special interest. A number of similar cases have been presented by different observers, and cases having so close a resemblance that they must be considered to be of like etiology. This group of cases, however, has a bearing of special interest, in that it represents a series, occurring within a comparatively short time, under different conditions, but alike in clinical manifestations. In looking back over the history of the hospital, a number of cases are brought to mind, by all connected with the institution, which, clinically, so closely resemble these as to be considered by them as undoubtedly of like origin; but in no instance, however, have they occurred in such a way that they could be regarded as a series, or grouped as regards their relation to time or etiology.

No attempt is made in the presentation of this series to formulate a definite theory as to their causation. At the present time, not enough is known about the physiological condition which results in the appearance of acetone and its allied compounds, to formulate a complete working theory. In the present state of knowledge, one can offer only the suggestions which have been given in the clinical presentation of the paper, and which point to the different conditions under which they have made their appearance. Neither is the opinion offered that the condition as seen, or that the fatal results, are due to an intoxication with acetone from its presence in the blood, for it is known that the same symptoms are present when ether allied compounds are found in the blood, urine and breath. It may be that the poison is not particularly injurious when acting on proteids in circulation, but becomes so when demanding its affinity from that which is fixed in the cells.

The object is to report, (1) The occurrence of these cases which give a distinct clinical evidence of being a form of acute intoxication, due in some way to a disturbance of the metabolism, and which has, among its peculiar manifestations, the presence of acetone and its allied compounds in the excreta. (2) The occurrence of these cases in a series or group, comprising twelve or more, in the course of a comparatively short period. (3) Their apparent occurrence under many conditions, but particularly fatal when following the administration of an anesthetic, and under cir-

cumstances which gave no reason to expect an untoward result.

This series of cases establishes certain facts. It can be stated positively that the symptoms are not the result of anesthesia, operation or shock, unless in the presence of certain underlying causes still undetermined. It is merely suggestive to say that most of the cases have occurred in children with a high-strung, nervous temperament. In such children the confinement, the changed habits, the changes in diet, the homesickness, the dread of operation, the anesthesia, and the operation itself, may lead to changes in metabolism which have not hitherto been taken into account. These changes may lead to serious or fatal consequences unless all the organs, including the muscular system, are not only sound, but performing their functions normally.

The fact that acetone is found in such very much larger quantities under various conditions without producing symptoms, and the fact that experimentally acetone can be injected into the blood of animals without producing symptoms, as has been shown above, prove that the presence of acetone is not the cause of the symptoms in the series of cases reported.

The fact that acetone had been very rarely found in the urine of the children in the hospital, except when there were the symptoms described in the cases reported, suggests that the toxic agent may be produced by the same conditions which cause the appearance of acetone in the urine, and that the appearance of acetone in the urine, in quantity sufficient to give the ordinary clinical reaction, is to be regarded as an indication of serious and possibly dangerous disturbance of metabolism.

In the cases reported, it is plain that the ordinary cardiac stimulants, brandy, strychnine, digitalis, proved useless. Acting on the assumption that the symptoms were due to an acid auto-intoxication, bicarbonate of soda was given to all the cases after acetone was found in the urine. Some of these cases died, though even to them the soda seemed to give sometimes temporary relief. Several of the children who recovered were seriously sick before the soda was given. So far as can be judged from the limited number of cases, bicarbonate of soda or some other alkali is the only remedy which promises to be of any decided benefit, and should be given in large amounts by mouth and in enemata. In some instances, the infusion of large quantities of salt solution under the skin or into the veins seemed to be of decided, though usually of only temporary, benefit.

This report is given with the hope that it may stimulate further and more careful observation of cases, for although one is not able to point to the definite origin of the disturbance, yet one may, in conclusion, give certain suggestions in regard to it which are gathered from a study of the different conditions under which the phenomena occurred. These suggestions are based upon circumstantial evidence, but point to the need of paying more attention to certain conditions in the hospital care of children, both operative and nonoperative. These are: First, that greater attention should be paid to temperament, and to the conditions which influence it, realizing the anxiety and fright, with the accompanying physical disturbances, caused by entering a hospital, remembering that these are particularly noticeable in children of high-strung and apprehensive temperament. Second, that the absence of any gross evidence of a pathological condition, as shown by heart murmurs, evident changes in the lungs and kidneys, or abdominal tumor, may not constitute immunity from the danger of acetonemia, and possible death after operation. Third, decided caution should be paid to those cases in which there may be reason to suspect a fatty condition of the liver. The reported experience of many writers, as well as that derived from those cases here reported, warrant this view. Fourth, it is more than probable that unusual care should be exercised in those cases showing extensive degenerative change, and, particularly, degenerative muscular change, such as is seen in extensive infantile paralysis. The large percentage of cases in this series, which present this condition, seems to indicate that special stress should be laid on this point.

CASE I. L. R., a boy, aged ten years, of Roxbury, entered the Children's Hospital on Oct. 6, 1903.

Excepting for measles, the child had always been well until an attack of severe infantile paralysis nine months before. He had in part recovered the power to use his arms, but there remained paralysis of some muscles of the back and abdomen, and complete paralysis with marked atrophy of all the thigh and leg muscles on each side. The urine was acid, clear in color, and free from sugar and albumen. The pulse was 100; the temperature 99.5.

Four days after entrance, up to which time he had been perfectly well, the boy began to vomit persistently. The bowels had moved freely. The vomitus was watery, of light greenish color, not fecal. The abdomen was soft, and not distended. This lasted for two days, and on the third, the condition was improved, and the vomiting nearly ceased. Toward evening the pulse became very weak and rose from 95 to 150. The temperature, which had been normal, shot up to 105.8. There was no response to stimulation. The child became unconscious, and died in about twelve hours.

Autopsy, Oct. 11, 1903. Dr. W. R. Brinckerhoff.

Body of a well developed, fairly nourished white boy, twelve years of age. Rigor mortis present. Pupils equal, of normal size. Subcutaneous fat 1 cm.

Peritoneal cavity: Surface smooth and glistening. Two greenish black coils of jejunum lie on the left side of the cavity at the level of the umbilicus. These two coils, respectively each 10 cm. long, are somewhat distended, and in the upper end of each coil is an intussusception. The invaginated portion of the gut is 1.5 cm. in diameter; the greenish black distended portions being 3 to 4 cm. There is not fibrinous exudate in this region. Appendix normal. Mesenteric lymph nodes normal. Diaphragm at normal height.

Pleural cavities normal.

Pericardium contains a few centimeters of clear,

straw-colored fluid. The epicardium on the posterior aspect near the auricular-ventricular groove presents a few 1-mm., cherry-red spots. Other valves and cavities normal. Myocardium normal in color and consistency. Heart weight, 120 gms.

Lungs: Air containing, crepitant and pink.

Spleen: Weight 40 gms. Consistence flabby; color light red.

Pancreas normal.

Liver: Weight 1,130 gms. Light yellowish brown; markings distinct. Gall bladder contains much bile.

Gastro-intestinal tract: Mucosa presents no ulcerations at any point.

Stomach contains bile, stained fluid and the mucosa on the summit of the folds is somewhat injected. Duodenum and first portion of jejunum normal. Twelve centimeters of the intestine above the first intussusception contains a greenish black tenacious material (changed blood). The distended bowel below each intussusception is filled with the same material, which extends to a point 20 cm. or more below. The remaining portion of the intestine contains rather fluid, normal contents. The mesenteric veins tributary to the intussusception are normal.

Kidneys: Weight 130 gms. Pale, reddish brown; capsule strips readily leaving a smooth surface. On section cortex is pale brown; markings distinct. Adrenals normal. Bladder normal.

Cranium not opened. Cord: Consistency normal throughout. On section in the lumbar region is a pin-point, reddish area in one anterior horn.

Anatomical diagnoses. — Double intussusception of jejunum. Punctate ecchymoses in epicardium. Anterior poliomyelitis (clinical).

CASE II. M. J. B., a girl, aged eight years, of Fitchburg, entered the Children's Hospital on Oct. 6, 1903. She had an extensive infantile paralysis involving most of the muscles of both lower extremities which came on five years before, and necessitated the use of crutches in walking.

On several occasions during the preceding year, the child had several very acute attacks of severe and persistent vomiting, accompanied by marked prostration and rapid pulse, and the physician in attendance stated that the condition of the child at the time of these attacks, very closely resembled that described to him as existing on the first day of the fatal one. The attacks were severe enough to cause considerable alarm as to their outcome.

The child seemed rather delicate, but was well nourished, and physical examination showed nothing abnormal aside from the infantile paralysis already mentioned. The urine was acid, with specific gravity of 1,020, free from albumin and sugar. The pulse was 100; the temperature was 100.

Four days after entrance the child was etherized, and three tendons were transplanted. The loss of blood was insignificant, though the operation and the application of the plaster bandages kept the child under ether about an hour and a half. The child took ether rather badly, being rather blue, and having a rapid pulse, but at no time during or immediately after the operation, was there ground for anxiety in regard to the condition.

During the recovery from ether the child vomited as usual, and then seemed comfortable, and in good condition till twelve hours later. She then suddenly began to vomit persistently. The vomitus was at first watery and light green in color, but later dark. The pulse became very rapid, jumping to about 190, the temperature rose to 106. The vomiting lasted for about thirty hours. The child, who had been restless, gradually sunk into a delirious stupor, and died forty-two hours after the operation, thirty hours after the vomiting began.

In this case no test was made of the urine for acetone or diacetic acid. It was clearly recalled afterward, however, that the peculiar odor of the breath was very strong. Stimulation had no effect.

Autopsy, Oct 12. Dr. H. A. Christian.

Body of a well-developed, well-nourished female child.

Pleural cavities are free from adhesions and contain a normal amount of fluid.

Pericardial cavity likewise normal. Heart: Weight 100 gms. Scattered over the surface of the left ventricle are about one dozen subpericardial ecchymoses from 1 to 2 mm. in diameter. Heart of normal appearance throughout.

Lungs: In the anterior portion of the mediastinum in the loose areola tissue there are numerous small gas bubbles, and on the surface of the anterior portion of the right lung there are several subpleural areas about 3 mm. in diameter, and 1 cm. in length, which are distended with gas. These suggest in course the distribution of some of the subpleural lymphatics. About these, as also about the gas bubbles in the mediastinum, there is no evidence of inflammatory reaction. The surface of both lungs is smooth. The lungs anteriorly are grayish pink; posteriorly darker red; are everywhere air containing. Anteriorly they are more evidently crepitant, though there is a distinct crepitation posteriorly. The bronchial mucosa is very slightly congested; there is no apparent exudation. Bronchial lymph nodes show no change.

The thymus is quite large, coming well down towards the base of the heart. However, it is not very thick, and there is no evidence of any pressure on the deeper tissues from this.

Abdomen: Subcutaneous fat well developed. Peritoneal cavity, particularly on the left side, contains a considerable amount of dark, sour-smelling fluid. This is seen to originate from the stomach, and greater curvature in the region of the spleen is completely digested away. (This is apparently a post-mortem change.)

Vermiform appendix normal, free from adhesions. Mesenteric lymph nodes show slight general enlargement. The intestines are contracted. Peritoneal surface everywhere smooth and glistening.

Spleen is of normal size; is smooth. Its surface is much discolored in places by the action of intestinal gas; it is soft and flabby; cut surface is grayish red. Malpighian bodies are not made out with distinctness. There is a moderate increase in the pulp. The spleen was exposed to the action of the gastric juice, and some of the softening may be due to this.

The stomach, with the exception of the area of self-digestion, appears normal, as do also the intestines.

Pancreas is normal.

Liver: Weight 510 gms. Surface is smooth and irregularly mottled with yellowish areas from 3 to 5 cm. in diameter, scattered over a reddish brown surface. Cross section is yellowish brown in color. Markings are indistinct. There are a few very small areas of a darker reddish color.

Kidneys: Of normal size; capsule strips readily leaving a smooth surface. From cut surface cortex appears to be of normal thickness, is greyish in color; glomeruli are visible as small reddish points; pyramids are redder in color, and their markings are quite distinct. The contrast between the two is quite sharp.

Adrenal glands normal. Bladder normal. Aorta normal. Genitalia normal.

Brain: Weight 1,360 gms. The meninges everywhere appear normal. There is no evidence of exu-

dation nor chronic thickening. There is no apparent increase of subpial fluid. The ventricles do not contain an increased amount of fluid and the ependyma is smooth. The choroid plexus are also congested, as are also the meningeal blood vessels. Section of the brain in the usual way reveals no lesion. There is no evidence, either by flattening of the convolutions, or pressure ring on the cerebellum, of increased cerebral pressure.

Spinal cord shows, particularly in the lower lumbar region, an atrophy of the anterior horn on one side. The blood vessels lie on the surface of the cord, are much congested. No other lesion found.

Anatomical diagnosis. — Chronic poliomyelitis, anterior.

Cultures. — One culture spleen — bacillus of colon group. Two culture liver — very slight growth of same.

None of three show any staphylococci or streptococci.

Histology. — Spinal cord: The anterior horn of one side shows marked atrophy with almost complete disappearance of the anterior nerve cells.

Anterior mediastinum: The loose tissues of the anterior mediastinum show an acute inflammatory process of slight degree, evinced by the presence of polynuclear leucocytes in the tissue, adjacent to the gas cysts described in the gross. Sections of this tissue stained by Gram-Weigert method show no micro-organisms. Sections of liver, spleen, kidneys and lungs are negative. From these sections it is evident that to the marked process in the cord there is added some slight acute inflammatory process in the anterior mediastinum.

CASE III. E. W., a girl, aged five and a half years, living in Fall River, entered the Children's Hospital Nov. 16, 1903. When a year and a half old she had a severe attack of infantile paralysis, which kept her in bed some time with a high fever. A very general paralysis of the muscles of the thighs and legs persisted with contracted fasciæ, causing permanent flexion of the thighs, for the section of which she entered the hospital. The child has been about on crutches for about a year. Otherwise, the history was unimportant and the physical condition showed nothing abnormal, except, as was afterwards found, a slight trace of diacetic acid in the urine. The pulse was 100; temperature 99.

On the day after entrance, early in the morning, fasciæ at the upper outer part of both thighs were cut by open incision. The operation was very short, and very little ether was used. A double plaster of Paris spica bandage was applied.

After operation the patient seemed comfortable and passed a little urine. At 11 P.M., about thirteen hours after operation, she vomited a small amount of dark-brown thin fluid, and during the next ten hours vomited similar material several times. She slept in all three hours during this time. While awake she was very restless and noisy.

Twenty-four hours after operation the condition of the patient was very poor. The extremities were cold, the pulse was weak and rapid, the expression was anxious. The peculiar sweet odor of the breath became noticeable during the morning. At noon, twenty-six hours after operation, five ounces of urine were passed. This contained large traces of acetone and diacetic acid.

The child had not responded well to stimulation by strychnine given subcutaneously. A pint of salt solution was then given intravenously, after which the child became more quiet, though the pulse did not improve. Thirty hours after operation the child began to be delirious. The pulse became scarcely perceptible at the wrist. Attempt to move the bowels by enemata and catharties were without avail, except for one small constipated movement.

Thirty-six hours after operation, twelve ounces of two-percent bicarbonate of soda solution was given intravenously, and also under each breast. Throughout this time there had been nausea, and occasional vomiting. Three hours later the child had an hour's sleep, and the pulse became more regular.

On the second morning after operation, the child became more dull and apathetic. She gradually lost consciousness. Coma came on. The odor of the breath became more and more marked as the condition became worse. The alæ nasi were working vigorously as though the child suffered from lack of air, and in the last few hours cyanosis was marked. The temperature after the operation remained about 102.

Autopsy, Nov. 19, 1903.

Body of female child, five and a half years of age. Well developed and nourished. No rigor mortis. No lividity. Pupils equal and normal, 3 mm. No edema. About 2 cm. subcutaneous fat.

Peritoneal cavity: No fluid nor adhesions. Serous membrane glistening and not congested. In mesentery of large intestine are numerous scattered small hemorrhagic points. Appendix is retrocecal, 7 cm. long. Mesenteric lymph nodes are not enlarged. Diaphragm at fifth rib or either side.

Pleural cavities negative. Pericardial cavity negative.

Heart: Fresh examination shows moderate amount of fat. Tissue is red, firm. Ventricles contracted, and the organ contains only a little fluid blood.

Lungs: Soft and crepitant. On section there is considerable white frothy exudation. The tissue is rich dark red, moist, crepitant everywhere. The bronchi are slightly injected. Bronchial lymph nodes are negative.

Spleen is firm and holds its shape well. Surface is dark red. The tissue is dark red, fairly firm, and only a moderate amount of pulp can be scraped off with the knife edge.

Gastro-intestinal tract shows nothing abnormal. The vessels are not congested. It contains little mucus, and a small amount of yellow feces. Pancreas is pale yellow and firm.

Liver: Surface smooth and pale yellow, and, in places, of reddish color. Stellate veins are in places well marked. Cut surface is pale yellow, oily and homogeneous. There are, in places, small, evenly distributed yellow areas corresponding with the centers of the lobules. The periphery of the lobules is pale red. The tissue is rather soft and friable. Fresh examination shows very marked fatty infiltration. Gall bladder moderately distended with brown bile.

Kidneys: Normal size. Capsule is thin and strips easily. Surface smooth and very pale yellow. In the section the lobulations are noticed, the cortex is very pale, yellowish, with some minute red points. The sub-cortical tissue is very dark red, and in marked contrast to the very pale red of the rest of the pyramids. Pelvis and ureters are normal. Fresh examination shows marked fatty infiltrations. Adrenals normal.

Bladder contains about 2 oz. of clear, straw-colored urine, which was drawn off in clean bottle with about 1 dr. of chloroform. Wall of bladder is negative.

Genital organs negative.

Aorta negative.

Organs of neck: Tachea and larynx are slightly congested. Thyroid normal. Thymus present, not large.

Brain: Calvarium thin, almost no diploe. Dura

only slightly adherent to bone. Slight congestion of meningeal vessels. No increase of fluid. Convolutions normal. Ventricles normal. Ependyma normal. Tissue not very moist.

Middle ears negative. Bone marrow red and soft.

Cultures from heart, spleen and liver were sterile. Cultures from kidney showed the colon bacillus.

DIAGNOSIS.

Microscopical description. — Heart negative. Lung and spleen show considerable acute congestion. Stomach negative. Small intestine shows many eosinophilic cells in the glandular epithelium. Pancreas negative.

Liver: Cystoplasm of liver cells is almost wholly replaced by vacuoles, both large and small, and what little there is stains poorly. The nuclei of the liver cells stain well. Many of the cells are phagocystic. Sections stained with Scharlach show very much fat.

Kidneys: The epithelium of the convoluted and descending tubules is swollen, vacuolated, and poorly stained. The nuclei stain well. Sections stained with Scharlach show considerable fat.

Sections of the thyroid, thymus, brain and pituitary body are negative.

Anatomical diagnosis. — Acetonuria. Very marked fatty infiltration of liver. Moderate fatty infiltration of heart and kidneys. Fatty degeneration of muscles of lower limbs.

CASE IV. M. S., a girl, aged eight years, of Boston, entered the Children's Hospital on Dec. 17, 1903. She had an extensive infantile paralysis of muscles of the right lower extremity, of seven years' standing. Otherwise, the child was in good physical condition. She entered at noon, was given dinner, and put to bed. In the afternoon she began to vomit, and continued to do so at intervals during the next forty-eight hours. On the evening of entrance the odor of acetone was detected in the breath. Next morning acetone and diacetic acid were present in the urine, the reaction being marked. The specific gravity was 1,020, sugar was absent; there was the slightest possible trace of albumin. During this time the patient had been restless, but on the second day after entrance, periods of stupor, from which the child could be easily roused, alternated with periods of restlessness, in which she cried out suddenly. A large part of the time she lay with her eyes open with a vacant stare.

Immediately after the onset of the vomiting nothing but hot water had been allowed by mouth. Enemata of salt solution and beef juice had been given every six hours. Peptonized milk and sodium bromide were later given by enema. Bicarbonate of soda was given in drachm doses every three hours from the day after entrance, at first by rectum, but after a week by mouth. The child slept nearly the entire third night, but on the following morning the vomiting began again and continued at intervals for the next three days, when it ceased entirely except for several times two days later. The vomitus was always watery and light green in color.

Aside from the facts mentioned, there were no other symptoms, and nothing abnormal could be found on physical examination. The abdomen was soft and not distended. The bowels moved freely. The temperature varied but little from 99. The pulse ranged about 100. The acetone and diacetic acid disappeared from the urine at the end of two weeks. The general condition had improved decidedly. Three weeks after entrance, the Achilles tendon was divided subcutaneously under local cocaine anesthesia, and a plaster bandage was applied. Ten days later this was changed under nitrous oxide anesthesia. The next day the over-corrected position of the foot caused considerable pain, but nothing else.

Twenty days later the child vomited again several times, and acetone again appeared in the urine, but only for a day. She was discharged well nine weeks after entrance.

CASE V. M. McL., a girl, aged six years, of Cambridge, entered the Children's Hospital on Dec. 17, 1903. When a year and a half old she had an attack of infantile paralysis, which had left her unable to walk. Except for fair power in the psoas and glutie, there was almost complete paralysis and atrophy of the muscles of both thighs and legs. The pulse was 110; the temperature 99. The urine was acid, specific gravity 1,025, free from albumin and sugar.

On the morning after entrance the child vomited once. The vomitus was watery, of light green color. Acetone and diacetic acid were not then present in the urine, but on the following morning both were present, and the child was very dull. There were no fever or other symptoms. Bicarbonate of soda was given in half-drachm doses every two hours. The condition slowly but steadily improved. After twelve days the acetone and diacetic acid disappeared from the urine. The bicarbonate of soda was continued during this time. After a few days the urine became alkaline. The after history was uneventful. Splints were fitted. The child was discharged five weeks later.

CASE VI. M. G., a girl, age four years, residence, Roxbury, was admitted to the Children's Hospital Dec. 26, 1903. Previous history was negative except for an attack two years ago. This illness lasted three days. The prominent features were absolute constipation for three days and vomiting. This was finally relieved by enemata.

Dec. 21, 1903, vomiting again began. Constipation had existed for some time previously. From Dec. 21 to Dec. 26 there was only one dejection. The vomiting occurred during this time frequently. Nothing, even water, was retained. Patient had become weak. Enemata had failed to relieve the condition of constipation. There was great thirst.

Dec. 26. On examination the patient was found to be weak. The face was somewhat haggard and anxious. Marked "acetone" odor to the breath. Abdomen somewhat distended and tympanitic; not especially tender. The physical examination was otherwise negative. Temperature 98.6. Pulse 140. The urine was clear, acid, specific gravity 1,024, albumin and sugar absent, acetone (marked) and diacetic acid present. Blood examination showed white count of 24,000.

Dec. 27. The vomiting has continued. Is now thin, light brown, foul smelling, *i. e.*, fecal in character. Patient has not been relieved by treatment, and attempts at feeding have failed. The abdomen is somewhat more distended and peristaltic movement of the intestine can be seen. The urine is clear, acid, 1,023, albumin 0, sugar 0, acetone (slight), diacetic acid. The patient was etherized, and the abdomen explored through a median incision by Dr. H. W. Cushing. A band formed by a Meckels diverticulum was found which extended from the ileum, in the vicinity of the cecum to the anterior abdominal wall, to the left of the median line near the umbilicus, completely obstructing the small intestine. This band was resected. One end was inverted into the ileum, which was closed over it by a "purse string" suture. The abdominal end was ligated close to the peritoneal attachment on the abdominal wall. The distal collapsed portion of the intestine immediately filled, and the obstruction was relieved. Examination of the rest of the intestine showed no other obstruction and

the abdominal wound was closed by sutures. The patient's condition at the end of the operation was quite serious and required free stimulation. That the "shock" was more pronounced, and the danger of the patient increased by the use of an anesthetic in the "acetonic" condition of the patient could not be definitely decided. There was good reason to expect marked shock in a case of this nature and duration, even had no anesthetic been used.

The patient reacted fairly well from the active stimulation, and during the afternoon and evening was quite bright. Temperature 100.4, pulse 150, fair quality.

Dec. 28. After 12.30 A.M. patient's condition became worse. Pulse was of poorer quality. There was gradually increasing stupor. No dejection. The abdomen rapidly became distended. At 9.45 A.M. (without anesthesia) the abdomen wound was opened, a loop of intestine found, and a rubber tube inserted for drainage, forming an artificial anus. Considerable liquid feces and gas drained off through this tube. The contents of the intestine had a marked acetone odor. The patient's condition became steadily worse. She was apparently unconscious, then comatose. The acetone odor in the breath increased. The pulse failed, and the patient died at 12.15 P.M. The urine (post-mortem specimen) showed a very marked reaction of acetone and diacetic acid. The temperature in this case was not especially elevated, while the pulse corresponded with the patient's general condition.

In this case two conditions existed: first, intestinal obstruction from mechanical cause; second, the "acetone" disturbance. This latter case indicated by the persistent vomiting, thirst, odor of breath, urine, stupor changing to coma without especial constitutional disturbance. The constipation, leucocytosis, abdominal distention, marked the condition of intestinal obstruction, which would cause the fecal character of the vomitus. The condition of the patient was quite serious immediately after the first operation, but after the reaction there seemed no reason why the patient should not recover, except for the disturbance from the acidosis; and it is probable that had not this existed the case would not have ended fatally.

CASE VII. T. D., a boy, aged seven years, of Melrose, entered the Children's Hospital on Jan. 2, 1904, with hip disease which had existed for nineteen months, but which had been very acute for only three weeks. An abscess had appeared. During the preceding two years there had been several attacks of diarrhea. The child also had measles and whooping cough and inflammation of the middle ear. Under rest and traction the acute symptoms about the hip subsided. The patient then got up and was walking about the ward with a Taylor hip splint. The pulse was 100; the temperature, 99. The urine was clear, acid, free from sugar, albumin and acetone and diacetic acid.

On Jan. 28, 1904, nearly four weeks after entrance, he vomited several times and was considerably prostrated. The characteristic odor of the breath was noticed. Acetone and diacetic acid were present for several days in the urine, which was rather high colored and had a specific gravity of 1,029. There were no further symptoms except a rise of temperature to 102.

CASE VIII. R. K., a boy, aged four years, of Boston, entered the Hospital on Jan. 27, 1904, for the radical cure of a left inguinal hernia. Aside from the hernia there was nothing noticeable in the history or physical examination. The boy was a Russian Jew, who neither spoke nor understood English, and apparently, as a result of homesickness, he cried almost constantly after entrance for several days. The urine was of normal color, acid, reaction, and free from albumin, sugar, bile pigment, acetone and diacetic acid. The urates were increased.

Two days after entrance, under ether anesthesia, a Bassini's operation was performed. The child recovered from ether well. Next day a sweet odor of the breath was noticed. Acetone and diacetic acid were present in the urine. There were no other symptoms except the constant crying and pulling off the dressings. There was no vomiting. After two days the acetone disappeared from the urine. While there was acetone in the urine the child was kept on a fat diet, and was given bicarbonate of soda by mouth. The child was discharged well in three weeks.

CASE IX. C. K., a girl, aged four years, of East Boston, entered the Hospital on Feb. 15, 1904. She had a congenital dislocation of both hips. On Sept. 4, 1903, a little over five months before, the right hip had been reduced by the Lorenz method. The etherization and convalescence were without incident. Since that time the right thigh had been kept in plaster. The plaster was removed. The skin was in fair condition. There were no excoriations. Otherwise the child was in good physical condition. The urine was acid, clear, and of slightly high color, free from sugar and albumin.

Three days after entrance, on Feb. 18, 1904, the child was etherized. In attempting by manipulation to change the right thigh from the first to the second position, the lower epyphysis of the femur was separated in spite of the fact that but little force was used.

An attempt was then made to reduce the dislocation on the left, when the same accident happened on that side. No further attempts at reduction were made. A double spica bandage of plaster was applied reaching to the toes. The child was under ether between a half and three quarters of an hour.

The child recovered from the ether as usual. There was but little nausea. In the evening the pulse was not strong; the rate had increased from 130, before the operation, to 150. The color was good and the skin warm. The child slept well. She had taken liquids. The bowels moved. She passed urine. There was absolutely nothing in any way unusual in the condition until six o'clock in the morning after the operation, an interval of twenty hours. The pulse at that time grew suddenly weak and rapid. The color became poor. A hypodermic injection of strychnine was given, and a few minutes later the color and pulse improved. The child seemed a little dull. There was no vomiting. The breath smelled sweet.

The condition improved, the color grew better, the pulse became stronger during the next three hours. There was another sudden relapse. The pulse became weak and rapid, the lips blue, the face looked drawn. Three ounces of urine were withdrawn by catheter. Acetone and diacetic acid were present. An enema of brandy, coffee and salt solution was given. The pulse improved a little. A half a drachm of bicarbonate of soda was given every three hours by mouth, and two drachms every three hours by rectum from this time on. During the day the child grew rapidly worse. She sank into a restless coma. The lips were very blue in spite of oxygen given freely. The drawn expression of the face increased, the eyes became sunken. She seemed to rally a little after the hot enemata were given. Considerable liquid was given

by mouth and retained, with the exception of vomiting a little milk once and a dose of soda once.

At 6 P.M. an injection of salt solution was given under both pectorals. Marked improvement followed in the pulse and in the color, and the child came out of the coma. At that time the temperature was 104. Only an ounce and a half of urine was obtained with the catheter. Hot poultices were applied over the kidneys. Urine was passed naturally at midnight and at 2 A.M.

At 9.30 P.M. the child was able to recognize her mother. At midnight, however, the condition again grew suddenly worse. The pulse grew weaker and more rapid; the respiration became poor. The temperature rose to 106 at 3 A.M. The coma returned. Stimulation by digitalis and strychnine subcutaneously, and by oxygen were of no avail. The child died at 5.30 A.M., twenty-three hours after the first collapse, forty-three hours after the operation.

Autopsy, Feb. 20, 1904.

Well-developed and nourished girl of three and a half years. Skin translucent white with marked lividity of the back. Flesh of body and thighs quite flabby. Body length, 95.5 cm. Slight rigidity in hands and feet. Five hours post-mortem. The layer of subcutaneous fat in the abdominal wall is 2 cm. thick.

Peritoneal cavity: Omentum short and contains little fat. No adhesions or fluid. Peritoneal vessels not congested. Intestines are moderately filled with greenish fluid. Mesenteric lymph nodes are slightly enlarged. Appendix hangs into pelvis, 5 cm. long, with short mesentery. Diaphragm is at the fourth rib on the left, and third intercostal space on the right.

Pleural cavity negative. Pericardium negative.

Heart: Normal size, tissue pale, fairly firm. Ventricles contracted, blood dark and fluid. Fresh examination shows a small amount of fat in the tissue.

Lungs: Soft and crepitant except in very posterior parts where the tissue is darker red and moist.

Spleen: A little large, rather firm, dark red, and the cut surface is moderately pulpy. Malpighian corpuscles quite numerous and distinct.

Gastro-intestinal tract: Stomach is partly filled with greenish-yellow liquid. Vessels of mesentery are congested. Mucous membrane apparently normal. Intestines are not remarkable. Pancreas normal size, tissue firm and straw colored.

Liver: Quite large, very pale yellow with a pink color in places. Veins on the surface are well marked. The cut surface is pale yellow and the lobules are indistinctly marked. The knife edge scrapes up much fatty material. The tissue breaks easily on pressure.

Gall bladder distended with green bile.

Kidneys: A little large; capsule strips easily, leaving a smooth surface. Cortex is pale red and 4 mm. thick; pyramids dark red. Fresh examination shows considerable fat in the epithelium of the convoluted tubules. Adrenals negative. Genital organs negative. Bladder contains about 30 cc. cloudy urine.

Bone marrow bright red.

All the muscles of both thighs are small, soft and flabby, and pale yellow.

Organs of the neck, negative.

Brain: Vessels of meninges congested. Brain tissue firm, quite moist and apparently normal. Moderate amount of fluid in the ventricles. Ependyma normal.

Anatomical diagnoses. — Extensive fatty infiltration of liver. Fatty infiltration of kidneys. Eosinophilia of gastric mucous membrane and spleen. Fatty degeneration of muscles of the thigh.

Cultures of heart's blood and spleen are sterile.

Bacillus of the colon group in liver and kidneys.

Microscopical examination. — Sections of the heart, lungs, pancreas, adrenals, ovary, thymus, thyroid, brain and pituitary body show nothing remarkable.

In the spleen there are some large phagocytic cells in the corpuscles, and there are numerous large cells, with generally one or two nuclei, which are filled with large eosinophile granules. Some of these are phagocytic.

In the epithelium of the peptic glands are many very large eosinophilic cells, in which there are numerour vacuoles and foreign bodies. In the small intestine these cells are very numerous, but there are few in the large intestine.

Liver: The nuclei of the liver cells are, in general, well stained, those of the connective tissue stain rather poorly. The liver cells are filled with vacuoles, which a section stained with Sharlach shows to be due to fat. Very little of the cytoplasm can be seen.

Kidneys: The epithelium of the convoluted tubules is broken down, stains poorly and is filled with vacuoles of fat droplets. The nuclei stain well. In the long tubules this is less marked.

In the bone marrow are numerous eosinophilic cells.

CASE X. R. H., a boy, aged six years, of Quincy, entered the Children's Hospital on Feb. 16, 1904. He had begun to walk at fifteen months. About the end of his second year it was noticed that he was lame, and as time went on he fell more and more frequently. When trying to rise he climbed up his own legs, grasping first an ankle, then by great effort a knee, and finally straightening up. Five months before entrance he recovered from pneumonia which came on after measles and whooping cough. Since then he had been unable to rise alone, although he could still walk when on his feet. During the three months before entrance his feet began to turn under him. He had been treated in the Out-Patient Department for sixteen months by massage.

On entrance he was only in fair physical condition. There was slight mental impairment. The expression was vacant; he was a mouth breather. The chest and abdomen showed nothing abnormal. The pulse was 100; the temperature 99; the respiration was 25. The muscles of the arm and shoulder girdles were much atrophied and weakened. The atrophy of the leg muscles was less marked. The feet were held in slight position of equino-varus. The gait was waddling and unsteady. The grip of the hands was weak. There were athetoid movements of the hands. The urine was acid with specific gravity of 1,018 to 1,028, and was free from albumin, sugar, acetone and diacetic acid and bile.

Three days after entrance, under ether anesthesia, both Achilles tendons were cut subcutaneously, and the feet were put in an over-corrected position in plaster-of-Paris bandages. Next day the child was comfortable and in no pain. The recovery from ether had been normal. Two days after the tenotomy the pulse was noticed to have jumped to 142, and the child seemed a little dull, with periods of restlessness. There was no pain, no nausea. The temperature and respiration were not altered. The sweet odor of the breath led to another test for acetone in the urine. It was found to be absent. Next day the child seemed to be better. The pulse dropped again to 100 within three days. Six days after operation the child was discharged to the Out-Patient Department without any unfavorable symptoms.

CASE XI. M.D., a girl, aged nine years, of Lowell, was admitted to the Children's Hospital on Feb. 18, 1904. She had been through measles and chicken-pox. She entered because of a valgus deformity of the foot, following an operation five years before for the correction of a congenital equino-varus. She was well

developed and fairly well nourished. Nothing abnormal was found on physical examination except the extreme valgus deformity of the right foot. The urine was acid, specific gravity 1,024 and free from albumin, sugar, bile, and acetone and diacetic acid. The temperature was 99; the pulse 100.

Two days after entrance the child vomited several times; complained that she felt sick, and seemed dull. The breath was sweet. Acetone was found in the urine.

She was at once put upon bicarbonate of soda, and given a diet as free from fat as possible. For the succeeding three days there was no acetone or diacetic acid in the urine. The child grew bright again. The vomiting ceased.

On the next day, the sixth after entrance, both acetone and diacetic acid again appeared in the urine, but there were no unusual symptoms.

Twelve days after entrance under ether anesthesia a complicated plastic operation on the foot was performed, and the limb part put up in plaster-of-Paris bandage. Considerable pain followed the operation, but there were no unusual symptoms and there was no reappearance of acetone or diacetic acid in the urine.

About three weeks later the child was discharged to the Out-Patient Department.

CASE XII. M. L., a boy, five years old, of Boston, entered the Children's Hospital on Feb. 23, 1904.

The child had been knock-kneed ever since coming to this country from Italy four years ago.

He was fairly well developed and nourished. There were a few râles in the back of both sides of the chest; otherwise the lungs and heart were normal. The abdomen was distended and tympatic. The rosary and the epiphyseal enlargements at the wrist and ankles were marked. There was a very prominent knock-knee due to a curve in the upper left tibia. The urine was normal in color, specific gravity 1,012, sugar, albumin, acetone and diacetic acid absent.

On the first two days after entrance the child vomited several times. The odor of the breath was sweet. The child complained of the throat and cried constantly. There was no collapse and no stupor. The temperature was elevated to 101 on the second evening, but at only one other time did it rise above 99.5. The urine showed both acetone and diacetic acid. This lasted for three days. There was no albumin or sugar at any time. The urine was acid except on one day after the soda had been given. The child was put on a fat free diet and given bicarbonate of soda.

The vomiting ceased in two days. There were no other unusual symptoms.

Twelve days later a Macewen's osteotomy of the femur was done, and the leg was put in a plaster-of-Paris spical bandage. The child was very noisy in coming out from ether. This was controlled by morphine. There was no recurrence of the acetone in the urine. Three weeks after the operation the bandage was renewed, and the child discharged to the Out-Patient Department.

CASE XIII. W. J., a boy, aged four years, of Roxbury, entered the Children's Hospital on Feb. 24, 1904, for the correction of double knock-knee. Three years before the child had chicken-pox and pertussis. Two years before had measles. He was markedly rachitic, but otherwise was in fair condition. Rosary and epiphyseal enlargements at the wrists and ankles were marked. The abdomen was distended and tympanitic. There was knock-knee on each side with forward and outward bowing of the tibia and femur. There was a coxa vara on the left. The heart and lungs were normal. The pulse was 90; the temperature 99, and respiration 30. The urine was acid, 1,026, normal in color and free from albumin, sugar, acetone and diacetic acid.

Two days after entrance a Macewen's osteotomy of both femora was done under ether anesthesia, and the legs were put in a plaster-of-Paris bandage from the toes to the umbilicus. The child recovered normally from the operation. Next day the odor of the breath led to the examination of the urine again. Both acetone and diacetic acid were present. There was no sugar or albumin. There was no rise of temperature. Within two days both the acetone and diacetic acid had disappeared. There were no other unusual symptoms at any time. The child was discharged three weeks later, still in plaster bandages, but with the legs in improved position and with good callus.

CASE XIV. E. P., a girl, aged three years, of Dorchester, entered the Children's Hospital on Feb. 27, 1904.

A year before she had pertussis. She came in because of pleuritic effusion following measles. She was well developed and nourished. The right chest was hyperresonant, but except for some moist râles in the lower back, the respiratory sounds were normal. The heart sounds were heard more plainly on the right than on the left.

On the left the intercostal spaces were bulging. The respiratory excursion was diminished. Respiratory and voice sounds and tactile fremitus were diminished except that there was bronchial breathing above the fourth rib. There was dullness in both back and front to the apex. The abdomen showed nothing abnormal. The temperature was 99.6; the pulse 122; the respiration 33.

The left chest was at once tapped and eight ounces of slightly cloudy, straw-colored serum were withdrawn. On account of coughing the needle was then removed. Next day she was transferred to the medical side. Afterwards two ounces more were withdrawn by a second aspiration. It was then found that there were signs of consolidation in the left apex, — dullness, broncho-vesicular breathing and numerous medium moist râles.

On the day after the tapping, the urine showed the presence of acetone though the reaction was not marked. There was no vomiting, no stupor, nor other unusual symptoms. She was given a diet without fat and was given cream of tartar and phosphate of soda, two drachms every four hours. The child was discharged from the hospital relieved, but still with dullness at the left apex two weeks after entrance.

Child showed no unfavorable signs or symptoms after aspiration of chest, no odor to breath noticed. The condition of acetone in urine would have been entirely overlooked except that in the course of routine examinations at that time acetone was found and in such small quantities that violet color not seen, or overlooked in foam, but urine gave a distinct violet reaction when dried on paper. This condition lasted through Feb. 29 (three days after entrance). Urine of March 1 showed not even the reaction on paper.

Reports of Societies.

AMERICAN GYNECOLOGICAL SOCIETY.

TWENTY-NINTH ANNUAL MEETING, HELD IN BOSTON, MASS., MAY 24, 25 AND 26, 1904.

FIRST DAY.

THE Society met in the Boston Medical Library, under the presidency of DR. EDWARD REYNOLDS of Boston.

An address of welcome was delivered by DR. CHARLES M. GREEN of Boston, which was responded to by DR. HENRY T. BYFORD of Chicago.

THE TREATMENT OF GALLSTONES FOUND AS A COINCIDENCE IN ABDOMINAL OR PELVIC OPERATIONS.

DR. JOHN G. CLARK of Philadelphia stated that among the unsettled questions in abdominal surgery, the treatment of gallstones found as a coincidence in abdominal or pelvic operations might be considered a debatable one. He followed the plan at present of removing gallstones which were found in the course of another operation, if the patient's condition permitted of this extra operation. Although it was stated that 95% of gallstones produced no symptoms, he believed that this statement should not be applied to cases as one met with them at the time of an operation. In his review of recent literature he had been especially impressed with the fact that knowledge of the early stages of cholelithiasis was very indefinite, and that many cases which came to operation for more or less urgent symptoms did not have the clinical symptoms of colic and jaundice, as usually taught in medical schools. In view of this hiatus in the early history of this disease, he believed that many symptoms now attributed to gastralgia, indigestion, functional disturbances of the gastro-intestinal tract, etc., would, as knowledge increased, be ascribed to the presence of gallstones with associated infection, which was so frequently found in cholelithiasis.

In referring to the etiology of gallstones, he said that three facts had been prominently established: (1) That the bile was not bactericidal; (2) that the micro-organisms in the gall bladder were predisposing, if not absolute, causative factors in the formation of gallstones; (3) when gallstones were present in the gall bladder, infection in that viscus was much more likely to take place.

He mentioned three general avenues through which nfection might enter the gall bladder: (1) From bacteria circulating in the general blood stream and reaching the liver through the hepatic veins; (2) by the direct passage of bacteria into the common bile duct from the duodenum; (3) by the transportation of bacteria from the intestine through the portal circulation.

He then recurred to the frequently quoted statement that 95% of gallstones did not produce symptoms, and showed from his own series of cases that in at least 50% there were varying symptoms from undoubted attacks of colic and jaundice to less pronounced gastro-intestinal symptoms. To justify operative intervention in cases which were not producing well-defined symptoms, the mortality and morbidity should be a very low one. In his own experience no death had occurred, nor had there been any serious complication referable to the secondary operation. In lieu of the fact that the additional operation did not seriously jeopardize the life of the patient, and also because he had seen two patients die from cholelithiasis a year or more subsequent to an abdominal operation, in which, had the routine exploration been made, the gallstones might have been easily removed, he believed that the best interests of the patient would be conserved if the gallstones were removed as a secondary part of another operation, in the event of their being found. He appended the history of twelve cases to his paper, in which the various operative points, as well as the significant facts in symptomatology, were elaborated.

DR. R. STANSBURY SUTTON of Pittsburg said that gallstones did not always produce symptoms which demanded or justified resort to operation. If they were encountered during the course of another operation, they had better be removed. There was a remedy, however, which obviated the necessity, in some instances, of surgical intervention, namely, kolalin. He had used kolalin in dozens of cases in which he had held operation in abeyance, and did not have to operate subsequently.

DR. GEORGE M. EDEBOHLS of New York had occasion at one time to operate on a woman who presented marked dyspeptic symptoms. In addition she had movable kidney, chronic appendicitis, and induration in the region of the gall bladder. He anchored the kidney, removed the appendix through a lumbar incision, pulled the gall bladder into the lumbar wound, and found the stone about four or five centimeters in length, pear-shaped, and nearly filling the gall bladder. The attending physician was positive that the gall bladder did not produce symptoms of stone in it. He would not let him remove the stone from the gall bladder. A year later he opened the woman's abdomen for some other condition, making an incision near the gall bladder. He investigated the gall bladder, found it was perfectly healthy, and that the large stone had either passed or had been dissolved. The treatment after the previous operation consisted of the use of olive oil for about a month, and whether this had anything to do with the passage of the stone, he did not know. At any rate, the stone had disappeared and had left no trace of its former existence.

DR. A. PALMER DUDLEY of New York emphasized the importance of looking beyond the gall bladder for trouble. He believed that stones were formed in the liver ducts themselves, and that from a stagnant circulation cholesterin nuclei formed, and that only a small proportion of stones were found in the gall bladder. He would not hesitate to go into the center of the liver. In fact, in the last case he had, in which the diagnosis of gallstones had been made by a medical confrère, he boldly went into the gall bladder, but found no stone. He found the duct dilated; he went

five inches into the right lobe of the liver, as far as he could reach with his finger, and packed the liver full with iodoform gauze, put an apron of gauze over it, and the patient was well to-day. He would explore the center of the liver in searching for such deposits.

DR. BROOKS H. WELLS of New York said that in the last few years he had used practically the same measures as those outlined by the essayist. A number of patients coming under his observation had complained of obscure symptoms of so-called functional indigestion. In them he found either disease of the gall bladder, an over-distended gall bladder from obstruction elsewhere, or trouble referable to gallstones. By making a small or large incision, as seemed necessary, cleaning out the gall bladder and draining it, the patients had obtained remarkable relief from the symptoms that were supposed to be due to functional indigestion.

DR. SETH C. GORDON of Portland, Me., said that when the abdominal cavity was opened for other purposes, and he was quite sure the patient could stand it, he would examine the gall bladder thoroughly, and if gallstones were found, he would remove them. He cited cases in support of this line of reasoning.

DR. HIRAM N. VINEBERG of New York said that under the influence of the teaching of Kelly he had been in the habit of doing what had been advocated by the essayist, but after hearing a discussion on gallstones in the common duct and in the gall bladder by one of the Mayos, he had changed his method. Simply opening the gall bladder and removing the stones did not effect a cure, as proven by three or four cases that occurred in his own practice. If the gall bladder was diseased, however, it should be removed.

DR. J. M. BALDY of Philadelphia said that gallstones existed in the gall bladder for years without causing any material discomfort, but that when infection occurred they were liable to give trouble. There was not the slightest question but that large numbers of cases of so-called stomach trouble or chronic indigestion sooner or later proved to be cases of gallstones or of gall bladder disease. With reference to removing gallstones when operating for some other intra-abdominal condition, the surgeon should consider the physical condition of the patient, the surroundings, etc., and as to whether the patient was willing to undergo the additional risk of a second incision for the gall bladder operation.

DR. WALTER P. MANTON of Detroit quoted Ochsner as saying that he had tried almost everything in the so-called cases of chronic dyspepsia without affording relief; yet after opening their gall bladders and removing gallstones which were found, the patients were cured. Dr. Manton had seen a number of such cases, and contended that the removal of gallstones, or the gall bladder, if diseased, was the thing to do. He did not believe there was any solvent ever invented which would dissolve gallstones.

DR. BEVERLY MACMONAGLE of San Francisco, Cal., stated that when the abdomen was opened for some pelvic or abdominal trouble, the operator should investigate the gall bladder. If gallstones had been making the patient ill, causing dyspepsia, or if there were adhesions around the gall bladder, one should operate. The conditions that arose in the pancreas as a consequence of gall bladder disease and of gallstones were serious, and if the surgeon could do something of a prophylactic nature, without adding to the risk of the patient's life, it was a wise thing to do.

DR. CLARK, in closing, said the formation of gallstones through bacteria had been clearly demonstrated by a series of experiments. He did not believe anyone would strongly advocate operation unless the gallstones were producing symptoms.

OVARIAN PREGNANCY.

DR. J. CLARENCE WEBSTER of Chicago reported a case of ovarian pregnancy. There was a right ovarian, irregularly-rounded swelling, measuring 7 by 8 cm. There was no evidence of rupture into the peritoneal cavity. The adhesions were recent. Sections of the ovarian swelling consisted mainly of extravasated blood and disseminated fragments of the chorion. No evidence of transformation of ovarian connective tissue into decidua was noted. It was certain that the pregnancy did not start in a Graafian follicle.

DR. J. WHITRIDGE WILLIAMS of Baltimore said there was no doubt that ovarian pregnancy occurred, but it was the rarest of all forms of extra-uterine pregnancy. In regard to the Muellerian origin of ovarian pregnancy, he was not quite convinced of it. While there was no doubt that Muellerian tissue might be found in the ovary, as mentioned by the essayist and confirmed by numerous observers, he thought it was going too far to advance that view in explanation of every case of ovarian pregnancy.

DR. JOHN T. THOMPSON of Portland, Me., referred to a case of ovarian pregnancy he had reported at a previous meeting of the society. He called attention to the nature of the structures in which pregnancy occurred, and to the frequency with which rupture might occur in the early days.

DR. EDWARD P. DAVIS of Philadelphia removed an ovarian pregnancy about a year ago, the histology of which had not been completely worked up as yet, although a diagnosis was made very early of the nature of the tumor from the enlarged ovary. The indications were that the pregnancy did not originate in the Graafian follicle.

DR. LAPTHORNE SMITH of Montreal had diagnosed ectopic pregnancy by the clinical symptoms; had operated, and found hematoma of the ovary. He had said to his students that he was sorry that his diagnosis was wrong, because authorities maintained that there was no such thing as ovarian pregnancy, but after hearing what had been said, he was convinced there was.

URETERO-LITHOTOMY.

DR. J. WESLEY BOVEE of Washington, D. C., in a paper on this subject, gave the history of the operation, and then discussed the size and number of calculi. The routes for reaching and extracting ureteral calculi, he said, were the transperitoneal and the extraperitoneal. The latter might be subdivided into loin, inguinal, vaginal, rectal, sacral, perineal, and transvesical. The transperitoneal route should never be the one of election, as the danger of peritoneal infection from the urine was too great. Of the extraperitoneal routes, the selection would depend largely upon the location of the calculus or calculi, although the operation of Ceci, of removing it through the rectum, should only be considered justifiable when the stone had practically sloughed through into the rectum. In a class of cases characterized by the stone having been lodged in the intravesical portion of the duct and later sloughed into a pocket in the bladder wall, which it had made for itself, the vaginal and inguinal routes were the only safe ones, although in so stating he was not unmindful of the number of cases in which suprapubic cystotomy had been done. He discussed the removal of the calculus from the ureter, and the methods for so doing; also the treatment of the ureteral opening.

Speaking of drainage, he stated that all ureterolithotomy wounds should be drained. This was because the urine was practically never normal, therefore rendering wound infection probable. The possibility of urinary leakage subsequent to operation afforded another positive indication for drainage.

NEPHRECTOMY FOR PRIMARY TUBERCULOSIS OF THE KIDNEY.

DR. HIRAM N. VINEBERG of New York read a paper on this subject. Tuberculosis of the kidney, both primary and secondary, was more frequently met with in women than in men, in the proportion of about two to one. It was different from what occurred in men; renal tuberculosis in women was rarely associated with tuberculosis of the genital organs. A cystitis in women that resisted the topical applications of the silver nitrate solution by the Kelly method should be looked upon with marked suspicion as being of tuberculous character, even though repeated examinations of the urine should show an absence of the tubercle bacillus. The differential diagnosis of a non-tubercular from a tubercular cystitis with the aid of a cystoscope was not as reliable as the therapeutic test outlined in the preceding sentence. Pronounced reddening or ulceration about the mouth of one of the ureters, with absence of other bladder changes, was held by some authorities as pathognomonic of tuberculosis of the corresponding kidney; while the sign was an important one, too much weight should not be attached to it in women. In most cases, the removal of the diseased kidney would bring about practically a cure of the descending cystitis. He doubted the wisdom of the advice to cure the cystitis before undertaking the removal of the kidney. In women, owing to the fact that the disease was most frequently primary and unilateral, the modern tests for determining the functional capacity of the second kidney were not so essential as in men. Catheterization of the supposedly healthy kidney was a procedure to be avoided, when, as was frequently the case, there was associated a tuberculosis of the bladder. The prognosis of nephrectomy in renal tuberculosis in women was exceedingly good. Of the writer's four cases operated upon, seven, five, two, and one and a half years ago, respectively, all were alive and in good health.

DR. JOSEPH E. JANVRIN of New York reported a case of a woman who had been ailing for two years with what was supposed to be a renal calculus. Before operating, Dr. Willy Meyer examined the woman, and agreed with him that the case was probably one of calculus in the pelvis of the kidney, with possibly calculi in the ureter. The kidney was removed, and it was found that its pelvis was infiltrated with tubercular deposits in the very early stage. The patient made a good recovery and was well to-day.

DR. J. WESLEY BOVEE said that if one read the proceedings of the late meeting of the German Congress, one would be impressed with the comparatively large proportion of cases in which primary tuberculosis was found in both kidneys, or the very small proportion in which one kidney alone was involved. As to the indications for operation, on tuberculous kidney, the surgeon should be sure that the opposite kidney was capable of carrying on the function of excreting urine for the whole body before he decided to remove one tuberculous kidney. A nephrotomy might be done, and the kidney most markedly diseased drained, without taxing the other kidney to a great extent. As regards cystitis in tuberculosis of the kidney, it was a late, not an early, symptom.

DR. PHILANDER A. HARRIS of Paterson, N. J., said that in cases of tuberculosis of the kidney it was difficult, where the bladder was corrugated and changed by the process present, to find the ureter; but by painting the entire field of the bladder with some solution sufficiently colored, with a swab, as Prussian blue, he had succeeded in finding the ureters, in the case of a girl, which he could not otherwise locate.

DR. SETH C. GORDON operated on a man, removing a kidney which was situated low down in the abdomen, painful, and bound down by adhesions. The patient died eleven days after the operation, and post-mortem examination showed that the man had no other kidney. Two years afterwards he removed a very large kidney from a woman, who lived twenty-eight days after operation. For twelve hours she did not have a single uremic symptom, nor was a drop of urine secreted, and she died in full possession of her faculties. Post-mortem examination revealed that she had no other kidney.

DR. J. M. BALDY said it was not uncommon to have medical men in the wards of the policlinic ask if the ureters had been catheterized in the cases of supposed kidney disease, and not infrequently a perfectly healthy kidney was palpated and found on one side, which utterly failed to secrete, with the patient under an anesthetic or without it. In some instances, this failure on the part of the kidney to secrete was undoubtedly brought about by the influence of the anesthetic. At any rate, anesthesia would reduce the quantity of secretion very materially. He had had exactly that same experience a number of times in patients whose ureters he had catheterized, but to whom no anesthetic had been given.

DR. GEORGE M. EDEBOHLS said that some four or five years ago he read a paper on "The Other Kidney and Contemplated Nephrectomy." In it he advocated that before removing a kidney an incision should be made on the opposite side to determine by actual inspection and palpation, first, the presence of another kidney, and second, its probable health, so far as could be determined macroscopically, before removing the diseased kidney. In spite of the advance made in diagnosis, and its limitations in kidney diseases, he had adhered to that rule in all nephrectomies performed since that time, and in one case he had saved a woman's life by so doing.

DR. J. RIDDLE GOFFE of New York reported a case bearing on the removal of the ureter in connection with tuberculosis of the kidney, the patient having been operated on by him in 1896. She was a woman of twenty-two, who had a very large tuberculous abscess of the right kidney. He removed the kidney and three inches of the ureter. She made an excellent recovery, excepting that she had a sinus which lasted four months and then healed. Patient was now a graduate nurse and in perfect health.

DR. EDWARD REYNOLDS of Boston gave his experience of 10 nephrectomies for tubercular disease, 7 of them being complete nephro-ureterectomies, all successful, so far as operative mortality was concerned.

HYPERTROPHIES AND INFLAMMATIONS ABOUT THE URINARY MEATUS.

DR. ROBERT L. DICKINSON of Brooklyn read a paper on this subject, saying that their frequency and the suffering caused gave them an importance out of all proportion to their minute size. Overlooked because hidden among folds of mucous membrane. They were explained by embryology. A tiny ribbon ran from the rear of the vaginal opening forward, on each side of the vaginal and urethral openings across the vestibule, to disappear beneath the clitoris. This fold was persistent in those cases where the hymen ran forward of the meatus, or the meatus seemed to open

on the anterior vaginal wall. This fold was enlarged by friction or traction to produce flaps or labia, hanging out each side of the meatus. They were found only with corrugated labia. Dilated or dilatable urethra often accompanied them. The urethral glands opened near the apex of the flaps. They were long, running down into the anterior column of the vagina. Swelling from infection differed from hypertrophy. The cure of chronic inflammation was only feasible by obliteration of the glands. A fine probe passed to the bottom of the gland rendered the vestibular-vaginal surface tense; the cautery wire cut out the probe. For piles of the meatus, the cautery wire was used after cocaine; for prolapse or dilatation of the urethra, resection of the anterior vaginal wall or paraffin injections into the urethro-vaginal septum produced a sigmoid profile.

AMERICAN MEDICAL ASSOCIATION. SECTION ON PRACTICE OF MEDICINE.

(Concluded from No. 26, p. 710.)

THIRD DAY. THURSDAY, JUNE 9. — (Continued.)

THE PATHOGENESIS OF UREA AND ECLAMPSIA.

DR. ROBERT N. WILLSON, of Philadelphia, presented this paper and offered the following conclusions: (1) That it is probable that there are at work in the cerebrum as well as throughout the system of uremia subjects, at least one, and probably several, toxic substances, which exert their influence more or less locally upon the cortex. (2) That it is equally certain that other portions of the brain than the cortex are also acted upon, as in the production of coma, etc. (3) That no small part in the production of the uremic and eclamptic condition is played by intracranial pressure, due to a temporary excess of fluid, whether acting independently of, or in conjunction with, the toxic substances already mentioned. (4) That lumbar puncture will at least temporarily relieve certain of the symptoms most readily ascribed to localized intracranial pressure; and that cases in which pressure is the main factor, drainage of the spinal canal may save life. The procedure, together with free bleeding, purging and diuresis, should be added to our routine treatment of the condition. (5) That transfusion of normal salt solution by intravenous injection or hypodermoclysis except in cases of anuria, or a greatly diminished urinary secretion, is contra-indicated, as tending to increase the liability to saturation of the tissues. (6) That the results of lumbar puncture in the three cases cited in the paper would not warrant the assumption that relief of intraspinal or intracranial pressure could alone be depended upon to cure the uremic or eclamptic condition, provided the toxic influences were prominent.

DR. JAMES TYSON, of Philadelphia, thought that we must consider some toxic agency responsible for the phenomena.

DR. ALEXANDER LAMBERT, of New York, said that in eclampsia the lesions noted were often identical with those of acute yellow atrophy of the liver.

DR. ROBERT N. WILLSON, of Philadelphia, emphasized the fact that when bloody fluid was withdrawn by lumbar puncture, the cases terminated fatally, whereas if clear fluid was obtained patients could recover.

AMEBIC DYSENTERY: ITS LOCAL LESIONS AND TREATMENT.

DR. JAMES P. TUTTLE, of New York, read this paper. His paper was based upon personal experiences of seventy-four cases of amebic dysentery, together with what he had gained from literature. The cause of the disease was the infection or invasion of the colon by amebæ dysenteriæ. At about the temperature of the body the life of the amebæ was indefinite, but if the temperature got below 70° F. the motility and life of the amebæ became extinct and no amount of heat would restore the same. He said the whole treatment should be directed toward the local lesions, the destruction of the amebæ and the prevention of a redevelopment from the spores, and as these were buried in the tissues it was evident that superficial washing or flushing of the intestinal canal would not destroy them. It is found that simple cold water served every purpose in destroying the amebæ. The patient was placed in the knee-chest posture, and the bag or fountain was elevated not more than three feet above the level of the hips and the fluid was allowed to run in slowly, the amount of water used being limited only by the tolerance of the patient. Local ulcers of the rectum and sigmoid were treated by local measures. Recognizing the fact that the appendix might be the seat of amebic infection he said it would be wise to remove this organ in those cases in which the appendix was utilized, to introduce the cold water into the large intestine. In seventy-three cases treated by this method cures resulted in seventy cases.

DR. FENTON TURCK, of Chicago, called attention to the futile attempts to destroy the amebæ, for it had been his experience that the various solutions had little, if any, effect upon them. He referred to the use of oil which acted as a powerful irritant and which excited peristaltic hyperemia and which had more or less effect upon the plasmodiums. It was his plan to use hot water, starting with a temperature of 115° F. and gradually raising it to 131°. After every treatment the amebæ disappeared. This then was followed by the use of ice water, and the results he obtained were far better than if he had used the ice water alone.

DR. A. W. WARDEN, of Union Hill, Weehawken, referred to the beneficial results that he has obtained from the use of chaparro or nargosa.

THE FAMILY PHYSICIAN AS A FACTOR IN THE SOLUTION OF THE TUBERCULOSIS PROBLEM.

DR. S. A. KNOPF, of New York, read this paper, and after referring to the conception of the family physician, said that he should be carefully trained in the early recognition of pulmonary tuberculosis and should make calls at regular intervals, whether the family was ill or not. The importance of periodic examination of the chest of each member of the family was dwelt upon, and the inauguration of necessary preventive measures at slightest indication of predisposition to tuberculosis. He appealed for more sanatoria, more special hospitals, better tenement buildings, etc., all of which were of such value in the eradication of this disease, particularly before another generation had passed. The family physician should not only be the medical adviser, but also the friend of the family, and it was the family physician and friend more than any other person who would be able to prevent the marriage of a consumptive or between consumptives.

HAS INFLUENZA BEEN A CAUSATIVE FACTOR IN THE INCREASE OF APPENDICITIS?

DR. PHILLIP MARVEL, of Atlantic City, referred briefly to both influenza and appendicitis, and gave a statistical review of the periods from 1884 to 1894 and from 1894 to 1904 as copied from the Episcopal Hospital and from the Pennsylvania Hospital. Com-

parison of these periods showed a great percentage increase of appendicitis in the latter period, and also the greater increase over all of the more important pelvic and abdominal inflammatory diseases reported in the former period. The rapid increase was not satisfactorily explained through our better knowledge of diseases. He made certain suggestions and abstracts, and said that whether they would enable us to arrive at fixed conclusions did not affect the following deductions: (1) That appendicitis had increased in the past five years much more rapidly than in either of the previous five-year periods studied. (2) That the accessory cavities are more frequently attacked, and when diseased, more likely to be aggravated by influenza than by other diseases. (3) That there is more than a possibility of the existence of chronic interstitial influenza, therefore a probability of its causative relation to appendicitis. (4) That the observations as set forth in the abstracts referred to must be admitted as a measure of proof in favor of the inferences drawn and the conclusion arrived at.

FOURTH DAY, FRIDAY, JUNE 10.

ANEURISM OF THE INNOMINATE ARTERY.

DR. ALBERT P. FRANCINE, of Philadelphia, read this paper, and in conclusion he said that a delayed and weakened beat in the right radial, absence of pulsation in the right temporal, a turgid external jugular, in association with paroxysmal attacks of dyspnea and pain at the root of the neck, or referred to the right side, were very suggestive of innominate aneurism. But the two signs to which the writer would like to call especial attention and which had not, so far as he was aware, been before described in this connection, were the regurgitant quality in the right radial pulse, and even more convincing are the signs of aneurism in the supersternal notch behind and above the right sterno-clavicular articulation in association with a distinctive angle of re-entry in the second interspace. Unless relieved by operation, these aneurisms sooner or later would rupture. The operation consisted in distal ligation of the right common carotid and subclavian, one or both, either consecutively or if necessary at the same time. In uncomplicated cases it had proved highly successful, the sac becoming obliterated by organized clot.

SYMPOSIUM ON ARTHRITIS DEFORMANS.

PATHOLOGY AND ETIOLOGY OF ARTHRITIS DEFORMANS.

DR. THOMAS MCCRAE, of Baltimore, read this paper and offered these conclusions: The uncertain state of our knowledge of arthritis deformans was dwelt on, and the importance of determining whether or not we had one or more diseases included under the term. The anatomical distinctions between the two types were described, but the view was expressed that these were varying manifestations of the same disease. This seemed to be supported by their occurrence in the same patient. The various theories as to etiology were gone over and the possibility of an infection being the cause was favored. There was as yet no positive evidence of a specific infection as against the possible casual agency of various ones.

SYMPTOMATOLOGY OF ARTHRITIS DEFORMANS.

DR. JAMES J. WALSH, of New York City, read this paper. He said that uric acid had nothing to do with rheumatic conditions. Rheumatic gout had disappeared, and there was no middle term between the two. Chronic rheumatism was vanishing. Arthritis deformans could be traced in history at nearly all times. The bones of bodies buried probably fifty-five hundred years ago show in certain cases the signs of the changes in arthritis deformans. Certain English authorities divided arthritis deformans into three groups as follows: (1) The disease commonly known as osteo-arthritis, often confined to the hip-joint and most common in old men. (2) A disease in milder form and often not recognized, most common in women in middle life and represented by deformities occurring in the terminal joints of the fingers. The deformity becomes considerable and ultimately due to bony outgrowth. (3) This form was one simulating ordinary acute rheumatism and produced lasting changes in the joints and had a certain tendency to recur, and ultimately made the victim hopeless and a pitiable cripple. It occurred more commonly in young women. Perhaps the most characteristic of the differential diagnostic symptoms was that the salicylates failed to reduce the fever very materially and failed to lessen the pain and discomfort. One of the most important features of this affection was its tendency to recur.

THE TREATMENT OF ARTHRITIS DEFORMANS.

DR. CLARENCE EDWARD SKINNER, of New Haven, Conn., said that what had given him the most satisfaction as a routine treatment, to be modified according to the conditions surrounding the individual cases, was as follows: (1) A diet as generous as could be digested and assimilated by the individual case, and consisting largely of red meats. (2) Rest in bed for at least ten hours out of the twenty-four. (3) A pill consisting of 1-40 of a grain of strychnia sulphate and 1½ grains of ferrous iodide three times daily, half an hour before meals, and in the emaciated cases one to four drams of cod liver oil three times daily, after meals. (4) A dose of some one of the mineral waters before breakfast two or three times a week if constipation was present. (5) A body dry hot air treatment two or three times weekly. (6) Central galvanization once or twice weekly. (7) A general application of mechanical vibratory stimulation two or three times weekly. (8) A static electrical application, at least once every day, consisting, in acute cases, of the Morton wave current localized over the affected joints or spine, and in the chronic cases of long, thick sparks to the affected joints one day and the Morton wave current localized over these joints the next. (9) With anchylosed joints wherein the acute condition had subsided and the functional impairment was not due to osteophyte formation, passive movements every day, in the form of alternate flexion and extension, the attempt being made to increase the excursion of the manipulated member each time, were of considerable use.

Fifty-one cases that had been treated in private practice during the past four years illustrated what could be done by the application of the treatment outlined. A practical and easily-comprehensible summary of the results obtained in these 51 cases were as follows: Out of 24 patients who were totally incapacitated for the performance of their daily duties, 6 were restored to a condition of unimpaired usefulness, 3 to a condition of but slightly impaired usefulness, and 8 of the remainder discontinued treatment prematurely; out of 27 who were partially incapacitated, 7 were restored to unimpaired usefulness, 4 but to slightly impaired usefulness and of the remainder 14 discontinued treatment prematurely. Out of 36 patients who were suffering constantly from pain, 10 were relieved entirely; in 12 the pain was relieved to such an extent as to be troublesome only ocasionally, and 11 of the remainder discontinued treatment pre-

maturely. Of 15 cases in which pain was present only on movement, 5 were relieved entirely, 3 were greatly relieved, and of the remainder 8 discontinued treatment prematurely. Of 11 cases in which complete anchylosis of one or more joints was present, complete relief was obtained in one or more joints in 2, partial relief in 4, and 5 discontinued treatment prematurely. Of 25 cases in which partial anchylosis of one or more joints was present, 13 were completely relieved, 12 partially and 11 discontinued treatment prematurely. Of 27 cases, wherein the general condition was bad when the treatment was commenced, 10 were restored to normal health, 12 were greatly improved; of 19 cases wherein the general condition was fair, 5 were restored to normal and 8 were greatly benefited.

DR. J. E. GOLDTHWAIT, of Boston, said that the nomenclature used was unimportant so long as we knew what was meant by the terms used. In arthritis deformans Dr. McCrae spoke of two types, the atrophic and the hypertrophic, but there were many cases encountered which he termed infectious arthritis. At times it was impossible to differentiate between the atrophic and hypertrophic at first glance; but with the radiograph it was now quite possible. In the disease described by Still, occurring in both children and adults, he did not know whether it was atrophic or hypertrophic in character; it seemed to be a matter of personal opinion. It seemed to him surprising that we should have these two types of the same disease, and one man had stated, and frankly too, that from the start the disease never became chronic, and others that at the start it was chronic and never became acute.

DR. ALLEN JONES, of Buffalo, did not believe we should throw out the term chronic rheumatism until we had demonstrated positively either the specific cause for acute articular rheumstism, or a specific cause for acute rheumatism and arthritis deformans.

DR. DELANCEY ROCHESTER, of Buffalo, said that the treatment advised by Dr. Skinner was practically out of the question for the general practitioner because of lack of the apparatus. Still he thought very good results could be obtained by them by carefully watching and handling these patients. He thought the application of hot air not so hot as advocated would be productive of good results. The use of the cabinet and friction was of value.

HOW THE GENERAL PRACTITIONER SHOULD TREAT GONORRHEA.

DR. FERDINAND C. VALENTINE, of New York, read this paper and offered the following conclusions: (1) Every general practitioner is practically competent to successfully treat uncomplicated anterior gonorrhea, if he will devote as much attention to this as he does to any one other disease. (2) Every patient with gonorrhea is entitled to the services of his family physician, just as much as if he had acquired any other disease in consequence of drunkenness or other violation of ethics or morals. (3) The general practitioner who declined to treat uncomplicated acute anterior gonorrhea avoids one of the most sacred duties to the profession and to humanity. (4) The patient who, because he has gonorrhea, is refused the services of his physician is likely to become an opponent to scientific medicine, to the detriment of his health, that of his family and of the community. (5) The scientific treatment of at least acute anterior uncomplicated gonorrhea is perfectly within the power of the general practitioner. (6) The irrigation treatment of gonorrhea is, as yet, the most effective method and most in accord with the modern scientific understanding of the disease.

PROBLEMS AND THE TUBERCULOSIS CONVALESCENT.

DR. A. MANSFIELD HOLMES, of Denver, Colo., read this paper. He said pure air and sunshine could avail but little if the patient was not provided with an abundance of suitable food. The wisest advice to patients would avail nothing if the patients are not sufficiently impressed with the importance of proper living, and it was in this that the sanatoria treatment surpassed the home treatment. The danger lay concealed in a latent form long after all subjective symptoms had disappeared. To form a correct estimate of convalescence one should form a composite picture of all the available clinical evidence. If there was a gradual gain in weight extending over a comparatively long period, if this gain was accompanied by a gain in strength, if the gain of weight and strength were permanent, and if the cough, sputum and bacilli diminished and finally disappeared, and if these conditions were maintained for a comparatively long period, a cure might be considered as practically established.

ELECTION OF OFFICERS.

For Chairman, Dr. Richard C. Cabot, of Boston; for Secretary, Dr. Joseph L. Miller, of Chicago. Executive Committee, Dr. Frank A. Jones, of Memphis, Tenn.; Dr. W. S. Thayer, of Baltimore; Dr. Alexander Lambert, of New York.

Recent Literature.

Mammalian Anatomy, with Special Reference to the Cat. By ALVIN DAVISON, Ph.D. 12mo. 1903. Philadelphia: P. Blakiston's Son & Co. pp. 250. 108 figs.

This little book offers an excellent brief introduction to the anatomy of the cat, and being based on the author's practical experience is well arranged and illustrated. Most attention is given to the skeleton. The majority of the illustrations are original and good, though the appearance of some of them is marred by the undue size of the lettering. Its brevity and clearness will recommend this work for use in elementary courses in anatomy in colleges, while the figures, from the author's directions, will give it a wider value. Professor Davison confines himself, except for a few interpolated explanations of wider aspects of his subject, to descriptive anatomy. We cannot but think that the value of this meritorious manual would have been much increased had the author laid more stress upon the fundamental morphological notions, which must underly all correct understanding of anatomical forms; for example, no student would suspect from his descriptions and diagrams that the heart is simply a contorted tube, or that there is a fundamental difference between the thyroid and the other so-called ductless glands. The volume is well printed, and supplied with a good index.

THE BOSTON
Medical and Surgical Journal.
THURSDAY, JULY 7, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

THE QUESTION OF IMMIGRATION AND PUBLIC HEALTH.

THIS country more than most others is exposed to a certain positive danger from the constant advent of foreigners, who either bring with them disease or else are of so low a physical standard that they are little able to maintain a reasonable degree of health on their arrival. Few problems are more difficult than the framing of just laws to meet the peculiar exigencies which immigration to this country presents. In the first place, freedom must be allowed if we are to remain faithful to our traditions, and in the second place it is no less a duty of the authorities to guard those already in the country against disease and incompetency through physical deterioration which a certain class of immigrants brings. The whole question has been ably discussed in a recent article by Dr. Allen McLaughlin of the United States Public Health and Marine Hospital Service, published in the *Popular Science Monthly*. He discusses the matter from the point of view of the physique of the immigrant, his destination and the presence or absence of incurable disease.

Of these three factors, the physique of the immigrant is regarded as by far the most important. It appears that good physical condition was much more general among immigrants twenty-five years ago than at present, when the great majority came from the strong races of Northern and Western Europe, in whom disease of an incurable character was exceedingly rare. Now such immigration has sunk into insignificance when compared with that of the Slavs, Italians, Hebrews and others from the more southerly countries of Europe. This has led to a perfectly defined deterioration in the physique of the immigrant, with a corresponding increase in the percentage of disease. According to present laws, immigrants, however physically defective, are still permitted to become citizens of this country, provided only there is reasonable certainty that they are not likely to become public charges. Those suffering from dangerous, contagious, or venereal disease, or from marked mental derangement, are, on the other hand, deported.

The next point of importance is the distribution of the immigrants. It is a well-recognized fact that individuals of low physical standard will herd themselves together in the most unsanitary parts of our large cities, whereas the strong are more inclined to scatter into smaller towns and to become useful citizens. Of the various races, it is interesting to observe that more Hebrews are sent to hospitals on arrival, proportionate to the number landed, than any other race, whereas a very much larger percentage, namely, 70% of this race coming to New York, remain in the city. More Hebrews are also deported than those of any other race. On the other hand, the Scandinavians are deported in a vastly smaller ratio, fewer are sent to hospitals, and only 18% remain in New York. Between these two extremes come the Italian, Slav and Irish immigrants, the Irish, next to the Scandinavians, being the most acceptable of the immigrant class.

A third factor, naturally of very great importance, is the presence of communicable diseases among the immigrants. The detection of these is by no means a simple matter and requires constant vigilance and skill on the part of the medical inspector. Of these diseases, trachoma is of the most importance because of its frequency. Eighty-seven per cent of the total number of cases of loathsome and dangerous disease is due to trachoma, and 10% to favus. A careful investigation of the presence of trachoma was begun in 1897, in consequence of which many steerage immigrants were found suffering from the disease and were deported. Various subterfuges were forthwith undertaken to avoid the medical inspector, largely through becoming temporarily cabin passengers. Thereafter, in 1898, cabin passengers were also inspected, which has led to much less evasion of the law. The steamship companies have been brought to a sense of their duty in the matter by being made subject to a penalty in transporting diseased immigrants. In 1902 statistics show that among the Syrians landed in this country, one in 66 suffered from trachoma, whereas but one in 4,173 of the Irish

were afflicted with the disease. Within these wide extremes the other types of immigrants are classed, with cases running from one to several hundred up to one to several thousand.

It is interesting to note that tuberculosis of the lungs is a rare disease among immigrants, probably due to the fact that the bulk of our immigrants come from agricultural districts, where tuberculosis is far less prevalent than in large cities. The situation after landing almost immediately changes, inasmuch as tuberculosis is quickly spread through the tenement districts among immigrants lately landed, due naturally to filthy surroundings, often poor general physique and overcrowding, with all that that entails. Dr. McLaughlin finds that the real danger to the public health from immigration lies in that class whose physical condition is far below American standards, and who take up a residence in the East Side tenements of New York City. In conclusion, the following excellent suggestions are made:

If we debar any undesirable class of immigrants under the law, we should endeavor to make the law as nearly perfect as possible and debar all undesirable classes. We debar the immigrant with trachoma, syphilis, leprosy or favus; also the insane, the epileptic and the idiotic, but we admit the immigrant with poor physique, unless it is so marked as to make him undeniably a public charge.

There should be but one standard of physique for the immigrant, no matter whether his destination be the Pennsylvania mines or the New York sweat-shops. The skilled laborer should be expected to possess the same rugged physique as is now expected of the unskilled laborer. The standard should be fixed by law by comparison with other well-recognized standards of physique, and should be sufficiently high to exclude all who could not beyond doubt make a living at hard manual labor. The wording of the law should be definite enough to make the medical certificate of poor physique equivalent to deportation.

This requirement of a definite physical standard in immigrants could be exacted without undue hardship of all unmarried male immigrants within certain age limits, for instance, eighteen to forty-five. In regard to families, comprising women, children and old men, in addition to males between the ages of eighteen and forty-five, each family should be required to have at least one member constituting its chief support who could comply with the physical requirements of the law. The law need not apply to parents coming here to join their children, provided the children have established a home here and presented evidence of ability to care properly for their parents.

If the thousands of recruits for the sweat-shop army which arrive each year could be thus checked for ten years, the present existing tenement house problem would solve itself. The terrible congestion of the tenements would be relieved; the scale of wages for the sweat-shop worker would be elevated, and the general sanitary conditions of life in such districts as the Lower East Side, New York City, could be improved sufficiently to reduce the menace to the public health from this cause to a minimum.

THE MEDICAL PRESS.

THE medical profession is quite used to the flattery and eulogy of orators, and accepts with good grace and sufficient humility what is continually being said of it. There is, nevertheless, a certain gratification in hearing the praises of the profession sung by a layman where no special call for such eulogy is apparent. For example, the Hon. S. W. McCall, in his address last week before the Harvard Phi Beta Kappa Society, made the following remarks:

The nobility of the work of a calling will elevate those who devote themselves to it. Take the profession of medicine. Undoubtedly, the physicians might flaunt their cures, might play with the lives of their patients for their own financial gain and might show the same sort of enterprise that is too often shown by editors. If it be said that the newspapers give the public that which it is willing to pay for and that the responsibility for the press lies with the people, the quack could make a similar plea, and if he possessed skill in his calling he might gain wealth by its degradation. But inspired in the mass by the noble ethics which the profession imposes upon itself, we see physicians risking their lives in battle to save while those about them are striving to kill; we see them exposing themselves freely to the more deadly perils of infection, drawing generously upon their own strength that they may give it to others; we see them, in short, a profession of heroes.

Congressman McCall's oration concerned itself with the newspaper press, in which he found much to criticize, as conducted at the present time, in spite of the high ideals which should stand back of the profession of journalism. His discussion was confined to the daily press, and took no note of what is being done in the journalism of special callings. We accept with gratification as essentially true what he said about the ideal of the physician in his attitude toward his professional work, and our modesty is not too great to tempt us to carry the simile a step further and allude to the really high standard toward which most of our medical journalism has striven, and which it has in general maintained amid many temptations and discouragements. The element of sensationalism rarely finds its way into medical periodicals which are read by the rank and file of the profession, and

it is certainly the exception to find that surrender to the commercial spirit which Mr. McCall so strongly deprecated in the daily press.

BOSTON FLOATING HOSPITAL.

The Boston Floating Hospital began its ministrations for the summer July 6. It is proposed to make daily trips down the harbor, provided the weather permits, except on Sundays, from this date to some time in September. On Sundays and every night up to eight o'clock in the morning the patients will be admitted to the hospital at Pickert's Wharf, East Boston, near the North Ferry. The trips of the hospital will be from City Wharf, South Ferry, leaving at 9.30 in the morning and returning about four. Patients will also be received at these hours. The limit of age for patients is six years, and the requirement for admission a certificate signed by a physician from the Floating Hospital office, 178 Devonshire Street, from many of the dispensaries and hospitals, and from physicians and agents of charity organizations in the city proper, as well as from greater Boston. Admission cards may be had by application.

This hospital has had many years of usefulness, and certainly this type of hospital, not only in this city but in others, fills a place which can hardly otherwise be supplied, and particularly, under the conditions now existing in Boston, is it desirable that infants and small children during the hot months should have some means of obtaining the fresh air and direction regarding food and other details which are so essential to the preservation of their health. The usual closing of the infants' hospital throws an added burden on the managers of the Floating Hospital, which it has hitherto borne with excellent results. The institution is largely a charity, and is dependent in great measure for its continuance upon the subscriptions of those interested in the undertaking. We regret at times the sentimentalism which appears to be inevitable in the conduct of this hospital, but that after all this is wholly a minor consideration in view of the unquestioned value to the community which the institution provides. We certainly wish for it this year, as heretofore, a satisfactory season, unhampered as far as may be by anxiety as to ways and means.

MEDICAL NOTES.

A Proposed Statue to Dr. William Elias B. Davis. — A statue in memory of Dr. William E. B. Davis, late of Birmingham, Ala., is to be erected under the auspices of the Southern Surgical and Gynecological Association of which Dr. Davis was the originator. It is proposed to have the statue ready by Dec. 1 in order that it may be unveiled at the coming meeting of the Southern Surgical and Gynecological Association.

President of the American Medical Association. — Regarding the election of Dr. Lewis S. McMurtry of Louisville to the presidency of the American Medical Association, the *New York Medical Journal* takes occasion to pay him the following tribute:

> There has been no lack of efficient and graceful occupants of the presidential chair of the American Medical Association, especially in recent years, but we venture to say that the president elected at the last meeting, Dr. Lewis S. McMurtry of Louisville, will bring to bear on the duties of his office such alertness of mind and such courtesy and forbearance as are rarely to be met with in a single individual.

Honors for Medical Men. — Dr. William S. Halsted, professor of surgery in the Johns Hopkins University, was given the degree of LL.D. at the recent commencement exercises at Yale University. Dr. Halsted this year delivered the address to the graduating class at the Yale Medical School.

Dr. Frederick H. Gerrish, professor of anatomy in Bowdoin Medical College, the author of the well-known textbook on anatomy, has received the degree of LL.D. from the University of Michigan.

The University of Dublin has conferred the doctorate of science upon Prof. F. Klein of Göttingen, Major R. Ross, professor of tropical medicine at Liverpool, and Dr. W. H. Thompson, King's professor of the institutes of medicine.

BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon, July 6, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 40, scarlatina 15, typhoid fever 8, measles 45, smallpox 0.

Bequests to Hospitals. — By the will of the late Mrs. Henry Whitman of Boston, public bequests amounting to upwards of $200,000 are made. The hospitals to be benefited are: The Children's Hospital, Boston, $10,000, for the endowment of two beds; the Home for Incurables, Boston, $5,000; Massachusetts Infant Asy-

lum, $5,000. In addition to these bequests $20,000 is left to the Society for the Relief of Crippled and Deformed Children.

BOSTON MORTALITY STATISTICS. — The number of deaths reported to the Board of Health for the week ending July 2 was 180, as against 168 the corresponding week last year, showing an increase of 12 deaths, and making the death-rate for the week 15.28. The number of cases and deaths from infectious diseases was as follows: Diphtheria, 41 cases, no deaths; scarlatina, 12 cases, 1 death; typhoid fever, 13 cases, 3 deaths; measles, 42 cases, 1 death; tuberculosis, 51 cases, 23 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 16, whooping cough 1, heart disease 23, bronchitis none, marasmus 3. There were 10 deaths from violent causes. The number of children who died under one year was 41, under five years 55, persons over sixty years of age 32, deaths in public institutions 65.

NEW YORK.

MEDICAL EXAMINATION OF STREET CLEANERS. — Dr. Woodbury, Commissioner of Street Cleaning, has made public the result of the medical examination which has been going on for some weeks among the sweepers employed in his department. Out of 1,872 men examined, 60 were found to be affected with tuberculosis, and 223 with chest affections liable to result in that disease, making a total of 283 cases, or about 15%.

IN MEMORY OF DR. JARED LINSLY. — Among the gifts to the University announced by President Hadley at the meeting of Yale Alumni, on June 28, was a bequest of $250,000 from William B. Ross of New York, of the class of 1852, in memory of the late Dr. Jared Linsly, a prominent and highly esteemed New York physician of the last generation. This fund is to be used for the construction of the much needed central section of the university library.

AWARD FOR HEROISM. — The first gold medal to be awarded for heroism in connection with the "Slocum" disaster has been presented, together with a handsome purse, by the coroner's jury in charge of the case, to Mary McCann, an Irish girl, sixteen years of age, who only arrived in this country on May 11. At the time the "General Slocum" was beached on North Brother Island she was convalescing from scarlet fever in the hospital there, and she personally saved the lives of five children and one woman. In rescuing the latter from the water she very nearly lost her own life, and when she and her struggling charge were at last dragged ashore by one of the hospital attendants, she was completely exhausted. It is gratifying to learn that the exertions of this brave young girl and the exposure to which she was subjected were not followed by any serious effects.

TRANSFERENCE OF ASSISTANT SANITARY SUPERINTENDENTS. — On June 29 there was a general "shake up" among the assistant sanitary superintendents of the various boroughs, Dr. Bensel being transferred from Manhattan to Brooklyn, Dr. Sheil, from the Bronx to Manhattan, Dr. Murray from Brooklyn to Queens, Dr. Moore from Queens to Richmond, and Dr. Sprague from Richmond to the Bronx. President Darlington announced that there was no politics in this general transfer, stating that it was made simply for the good of the service and after a consultation with the chief sanitary superintendent, Dr. Roberts, and other officials. It was thought advisable, he said, that the assistant superintendents should become familiar with the work of the department in boroughs other than those in which they had been serving, and the change was designed as only a temporary one, as it must necessarily put the physicians to some inconvenience to do duty at considerable distances from their homes.

EXCITEMENT OVER A CASE OF SMALLPOX. — Much excitement was recently caused among the thirty families living in a tenement house on upper Third Avenue, by the death, in the house, of an Italian from smallpox. It became necessary to call upon the police to preserve order and compel the tenants to submit to vaccination. The patient had arrived from Europe only thirty days before his death, and was attended by a man known only as "Tony," who admitted that although he had been practising among the Italian families of the Bronx as such, he was not a qualified physician. The case was concealed until after the patient's death, and the way it became known was through Tony's asking Dr. Granna, a neighboring physician, for a death certificate, for which he offered to pay three dollars. Failing to obtain this, Tony thought it advisable to disappear, and no trace of him has as yet been found. This is the first case of smallpox which has occurred in the Bronx during the present year, and the house in which it occurred contained about three hundred persons.

Appointment of Miss Jane Delano at Bellevue Hospital. — It appears from a ruling given last month by the Municipal Civil Service Commission, that Dr. William P. Spratling of the Craig Colony for Epileptics at Sonyea, who was recently appointed superintendent of Bellevue Hospital, New York, was not eligible to that position because he had not been subjected to a civil service examination. It was then open to the trustees of Bellevue and Allied Hospitals either to appoint a superintendent from among those persons already holding positions at Bellevue, or to transfer to the head of Bellevue some one connected with one of the other hospitals under the jurisdiction of the Board of Trustees. It is now announced that the appointment has been given to Miss Jane Delano, who for several years has been at the head of the Bellevue training school for nurses. Miss Delano was graduated from the Bellevue school in 1886, and in 1888 took charge of the yellow fever hospital at Jacksonville, Fla. The year following she was made superintendent of the Copper Queen Mining Company's hospital at Bisbee, Ariz., under the direction of Dr. Thomas Darlington, now president of the New York Health Department. While there she was appointed assistant superintendent of the hospital and training school for nurses of the University of Pennsylvania, where she remained for six years.

Obituary.

THEODORE F. BRECK, M.D.

Dr. Theodore F. Breck, medical examiner for the Second Hampden District, died in Springfield, June 26, in his fifty-eighth year. His great-great-grandfather graduated at Harvard in 1742, and was a prominent physician in Western Massachusetts. His father also was a physician, graduating from Harvard in 1854. Dr. Breck graduated at the Harvard Medical School in 1866, and studied thereafter in Vienna and Paris. Returning from Europe in 1869 he began medical practice in Springfield, and there remained up to the time of his death. Since 1870 he was surgeon of the Boston & Albany Railroad, and since 1877 medical examiner for a part of Hampden County. He also served for twenty-four years on the staff of the Springfield Hospital, from which he had but recently resigned. He was a member of the Massachusetts Medical Association, the Massachusetts Medico-Legal Association, the National Association of Railway Surgeons, and various other medical organizations.

Miscellany.

MEDICAL ASPECTS OF THE WAR IN THE EAST.

Sir Frederick Treves, writing from Tokyo, publishes in a recent number of the *British Medical Journal* certain comments, in part as follows, on the war now in progress:

Thanks to the kindness of Surgeon-General Koike, the Director-General of the Army Medical Service, I was able to visit military hospitals and to learn something of the organization of the service he so ably controls. There is at Tokyo, also, Lieut.-Col. Macpherson, R.A.M.C., who is the medical attaché appointed by the English War Office, and his report of the condition of the Japanese Army Medical Service will be of great value and interest. Nursing sisters are not employed by the Japanese Medical Corps, nor indeed have female nurses any part in the organization of the department. The field equipment of the Army Medical Corps in Japan is excellent, light, simple, and inexpensive, and full of ingenious devices in almost every department.

In times of war the Red Cross Society supplements the medical work of the service. This society is remarkable in its size, its many branches all over the country, its important work, and its very admirable organization. It is a society of voluntary workers, has no direct official connection with the Army Medical Corps, but the utmost use is made of its invaluable services.

It not only maintains hospitals for soldiers in Japan, but it supplies an immense staff of civil surgeons and nurses. More than that it concerns itself in every way with everything that relates to the comfort of the soldier in times of war. The officers, non-commissioned officers and male sick attendants accompany the troops to the front. The military hospitals in Japan are thus emptied of their staff and are taken over by the Red Cross Society. That society provides civil surgeons for these hospitals and female nurses. The nurses are, of course, Japanese, and are well trained. Three years' training is required. The Red Cross Society is able to supply through its various branches no less than 3,000 female nurses and 2,000 male nurses. Female nurses will not be sent to the front, but will undertake duty in Japan in the military and Red Cross hospitals in various parts of the country. It is needless to say, therefore, that the military authorities need neither surgeons nor nurses, and it is difficult to understand how foreign nurses with no knowledge of the language and little insight into Japanese modes of living could be made use of. Pecuniary support to the Red Cross Society is the most practical way of helping the Japanese in their efforts to provide liberally for the sick or wounded soldier.

During a residence of two months in Japan I have been greatly struck by the admirable bearing of the people — in all classes of society — in connection with the war. The Japanese are intensely patriotic, but their patriotism is a solemn sentiment and not a temporary neurosis. There is no boasting and no bragging, and no symptom or trace of "Mafficking." In discussing their successes they are always modest, and their attitude towards an enemy who has experienced a temporary reverse is almost sympathetic. If the attitude of a people during a time of war can be discussed as a matter of taste, it may be appropriate to say that the attitude of the Japanese has been characterized by such good taste that it is worthy of imitation.

Deaths reported, 3,378; under five years of age, 924; principal infectious diseases (smallpox, measles, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 839; acute lung diseases 264, consumption 388, scarlet fever 28, whooping cough 7, cerebrospinal meningitis 55, smallpox 1, erysipelas 6, puerperal fever 9, measles 41, typhoid fever 36, diarrheal diseases 251, diphtheria and croup 65.

From whooping cough, New York 1, Chicago 4, Baltimore 1, Pittsburg 1. From smallpox, Philadelphia 1. From cerebrospinal meningitis, New York 48, Pittsburg 3, Providence 1, Worcester 1, Lowell 1, Chelsea 1. From typhoid fever, New York 7, Chicago 6, Philadelphia 7, Baltimore 3, Pittsburg 9, Boston 2, Cambridge 1, New Bedford 1. From erysipelas, New York 5, New Bedford 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending June 11, the death-rate was 14.1. Deaths reported 4,136; acute diseases of the respiratory organs (London) 64, whooping cough 124, diphtheria 38, measles 202, smallpox 7, scarlet fever 25.

The death-rate ranged from 7.0 in Walthamstow to 25.6 in Warrington; London 13.3, West Ham 11.8, Brighton 14.5, Southampton 10.7, Plymouth 9.2, Bristol 12.2, Leicester 11.6, Nottingham 11.9, Birkenhead 12.7, Liverpool 20.5, Bolton 9.8 Manchester 16.3, Salford 18.4, Bradford 14.8, Leeds 15.6, Hull 17.7, Sheffield 14.2, Cardiff 11.8, Rhondda 19.2, Wigan 18.3, Merthyr Tydfil 13.6, Kings Norton 11.0.

METEOROLOGICAL RECORD.

RECENT DEATHS.

SAMUEL LEONARD ABBOT, M.D., M.M.S.S., died in Boston, July 1, 1904, aged eighty-six years.

CHARLES S. WOODWARD, M.D., of New York, died at Glens Fall, N. Y., on June 26, after a lingering illness. He was a native of Michigan, and thirty-five years of age. He was graduated from the medical department of the University of the City of New York in 1891.

ROLLIN H. BURR, M.D., of Middletown, Conn., an instructor in the Yale Forestry School, was drowned in the Delaware River, near Port Jervis, N. J., on July 1, while saving the life of one of his pupils, who was upset in a canoe. He was camping on the river bank with a party of thirty students for training in athletics and the enjoyment of outdoor life, and had just finished a lecture on First Aid to the Injured, when the accident occurred. The young man whom he rescued was resuscitated, but Dr. Burr's body was not found for a considerable time.

TREASURY DEPARTMENT.

BUREAU OF PUBLIC HEALTH AND MARINE HOSPITAL SERVICE,

WASHINGTON, D. C., June 29, 1904.

A board of officers will be convened to meet at the Bureau of Public Health and Marine Hospital Service, 3 B Street, S. E., Washington, D. C., Monday, October 3, 1904, at 10 o'clock A.M., for the purpose of examining candidates for admission to the grade of assistant surgeon in the Public Health and Marine Hospital Service. Candidates must be between twenty-two and thirty years of age, graduates of a reputable medical college, and must furnish testimonials from responsible persons as to their professional and moral character. The examinations are chiefly in writing, and begin with a short autobiography of the candidate. The remainder of the written exercise consists in examination on the various branches of medicine, surgery and hygiene. The oral examination includes subjects of preliminary education, history, literature and natural sciences. The clinical examination is conducted at a hospital, and when practicable, candidates are required to perform surgical operations on a cadaver. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order as vacancies occur. Upon appointment the young officers are, as a rule, first assigned to duty at one of the large hospitals, as at Boston, New York, New Orleans, Chicago or San Francisco. After five years' service assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Promotion to the grade of surgeon is made according to seniority, and after due examination as vacancies occur in that grade. Assistant surgeons receive sixteen hundred dollars; passed assistant surgeons, two thousand dollars, and surgeons twenty-five hundred dollars a year. When quarters are not provided commutation at the rate of thirty, forty and fifty dollars a month, according to grade, is allowed. All grades above that of assistant surgeon receive longevity pay, ten per centum in addition to the regular salary for every five years' service up to forty per centum after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual expenses. For further information, or for invitation to appear before the board of examiners, address

SURGEON-GENERAL,
Public Health and Marine Hospital Service,
WASHINGTON, D. C.

Address.

ANIMAL EXPERIMENTATION.[1]

BY HAROLD C. ERNST, A.M., M.D.,
Professor of Bacteriology in the Harvard Medical School.

WHILE thinking upon the subject I have been asked to treat to-day, I chanced upon the editorial comment of *The Outlook* on two papers it recently published concerning animal experimentation, or, as it is there called, vivisection.

This comment seems so pertinent, that I have ventured to transcribe a portion of it, for it is well to show at the outset that the position I may take in this matter has the very recent support of high ethical authority.

After speaking of the nature of the articles printed, the comment goes on to say:

"Man's relation to the lower orders of creation is accurately expressed in the account by the ancient prophet, who wrote the account of creation in the first chapter of Genesis: 'And God blessed them, and God said unto them, Be fruitful, and multiply, and replenish the earth, and subdue it: and have dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth.'

"The animal creation is made for man, and he has a right and a duty to use it in whatever way will best minister to his highest life. He has not a right to treat animals cruelly, because all cruelty is wrong, and because cruelty does not minister to man's highest life but dishonors and degrades and deteriorates him.

"But with this definition, which is a definition and not a qualification, the fish of the sea, and the fowl of the air, and every living thing that moves upon the earth are subservient to man, and to be used by him. He has therefore a right to hunt and to fish, to slay and to eat, to use the horse to carry burdens and the dog to watch his flocks, the bee to hive his honey, the hens to lay eggs for him, the birds of the air to sing to him; and by the same right, he may use them in vivisection, if such use will minister to the health, the life, the welfare of the human race.

"There are two and only two questions involved in the problem of vivisection. The first question is, Does it minister to the health, the life, the welfare of the human race? To this there can be but one answer, the affirmative one. Then it ought to be practiced under such conditions as will make its ministry to man the greatest, its pain to animals the least.

"The second question is, What are these conditions? Vivisection before pupils in the grammar school, vivisection merely to gratify an idle or morbid curiosity, vivisection which has no health-giving end in view, vivisection which is regardless of and indifferent to the suffering of the animal is wrong, because it does not really minister to human well-being. The vivisection of science, the vivisection which is really seeking to learn the secrets of life and death, vivisection pursued with serious purpose in order to alleviate human suffering, and to prolong human life, vivisection carried on under conditions that reduce as far as possible the suffering of the animal operated upon, deserves commendation, not criticism, and its practice under these conditions belongs in the rank of the great modern philanthropic achievements." — *The Outlook*, April 9, 1904.

This comment might easily be extended, so far as the good sought is concerned, for many results from animal experimentation have been secured that have tended to the marked benefit of the lower animals and not to that of man.

"We must take the Universe as we find it. It is one in which life is constantly destroyed, doubtless for the benefit of other lives. As the highest type of the animal species, we at least need not be consciously cruel, but we should be blind to the teachings of Nature and invite race destruction if we did not seek to strengthen our species by endeavoring in every way to provide for it safeguards against the ravages of the lower types of life." — Editorial, *Boston Herald*, March 8, 1900.

All other animals claim, without hesitation, the destruction of other species than their own for their own benefit. It is doubtful if any wild animal, at any time, ever dies a natural death, always one of violence or starvation. Man does not at any time hesitate to claim his right over other animals to use them for pleasure, for decoration, for service, or for food. How, then, should he hesitate to use them — as in many heroic instances he has used himself — for the benefit of the human race?

That this latter has occurred in innumerable instances, the history of every epidemic shows, and the moral heroism thus demonstrated is all the greater in that it does not receive recognition. One of my most honored medical brothers — since passed on to his well-earned rest — once offered himself to me for a demonstration that, if attempted, he knew and I knew would result fatally. I have never passed through a more solemn or elevating scene than when this example of moral heroism was presented to me.

For the advance of knowledge, and for the better relief of suffering, animal experimentation must go on; there is no alternative. Few of my hearers will take the position of one active opponent of the practice that she would prefer to die rather than benefit by its results; and none, I hope, would repeat the blasphemous declaration that they would rather see a crucifixion than that it should go on.

The clear position of the loving parent is, "Just in proportion as I love my own children, I am willing that certain guinea pigs should be experimented upon for their sakes. I am not willing that a single guinea pig should be tortured needlessly, but I want the man who takes the life of my child in hand to do no needless experimenting upon the child in order to save guinea pigs." (Rev. W. E. Barton, March 9, 1900, quoted by H. C. E., BOSTON MEDICAL AND SURGICAL JOURNAL, June 14, 1900.)

[1] Read at the Annual Meeting of the American Social Science Association, Huntington Hall, Boston, May 13, 1904.

Speaking upon this subject, one of the clearest writers of the day says: "The insidious growth of selfishness is a disease against which men should be most on their guard; but it is a grave though a common error to suppose that the unselfish instincts may be gratified without restraint. The fatal vice of ill-considered benevolence is that it looks only to proximate and immediate results without considering either alternatives or distant and indirect consequences. A large and highly respectable form of benevolence is that connected with the animal world, and in England it is carried in some respects to a point which is unknown on the Continent. But what a strange form of compassion is that which long made it impossible to establish a Pasteur institution in England, obliging patients threatened with one of the most horrible diseases that can afflict mankind to go — as they are always ready to do — to Paris, in order to undergo a treatment which what is called the humane sentiment of Englishmen forbids them to receive at home! What a strange form of benevolence is that which, in a country where field sports are the habitual amusement of the higher ranks of society, denounces as criminal even the most carefully limited and supervised experiments on living animals, and would thus close the best hope of finding remedies for some of the worst forms of human suffering, the one sure method of testing the supposed remedies, which may be fatal, or which may be of incalculable benefit to mankind! It is melancholy to observe how often sensitive women, who object to field sports, and who denounce all experiments on living animals, will be found supporting with perfect callousness, fashions that are leading to the wholesale destruction of some of the most beautiful species of birds, and are, in some cases, dependent upon acts of very aggravated cruelty." (W. E. H. Lecky. The Map of Life, 1889, pp. 36 and 41.)

For some time *The New England Anti-Vivisection Society Monthly* (now known as *The Animal's Defender*) published the following: "What is vivisection, and what can I do to help the crusade against it? Answer: Vivisection is the mutilating, cutting and burning of living animals; they are dissected, roasted, boiled and skinned, when alive *and in full possession of their faculties* [italics mine]. Nerves are dissected out, laid bare and connected with the poles of a powerful battery, from which currents of electricity are passed over these nerves; this probably causes the greatest agony of which sentient beings are capable. The New England Anti-Vivisection Society opposes vivisection, (1) because the number of animals vivisected, with unknown and inconceivable agony to each one, is probably several thousand each day; (2) because anesthetics are very seldom efficiently used; (3) because the results of vivisection are as near to absolute worthlessness as it is easy to get, in fact cause great and absolute harm; (4) because, as recent revelations in the *Transcript* (1889) and other papers abundantly show, vivisectors of prominence and supposed character are, almost without exception, untruthful, and cannot be relied upon to tell the truth about their own acts," — and so on. These statements are so positive, and, if true, would be so overwhelming, that it is hardly conceivable that they would have been put forth with no better evidence to support them than has been offered from time to time. Full hearings have been given upon this subject by joint committees of the Massachusetts legislature, not only in one year, but for five successive years. Every opportunity has been given for the presentation of any specific evidence of cruelty or of the abuse of the practice of animal experimentation within this Commonwealth. The result has been uniformly the report of the committee giving "leave to withdraw" to the supporters of the various bills that have been presented favoring further legislation in restriction of or abolishing animal experimentation. If any portion of these statements of fiendish cruelty and useless experiment had been shown to be true, such a result before these successive committees would have been impossible.

None of the statements in the extract from the Anti-Vivisection magazine are specific of individual cases; only when this happens is it possible to make specific replies. The well-known case of Bayliss *v.* Coleridge is one in point and demonstrates how inaccurate, supposedly accurate observation may be; the circumstances should be of interest to all those concerned in the advancement of medical knowledge. They may be summarized briefly as follows: Two young Swedish women, of good education and social position, had been visiting various laboratories and attending lectures in courses on physiology, apparently with the purpose of securing evidence to be used in propaganda against animal experimentation. During the winter of 1902–03 they visited London, and in February, 1903, at one of a course of lectures in physiology at University College, they claimed to have witnessed experiments that were conducted with great cruelty and in violation of the law. They were at this lecture, as they had been at others, not as genuine students of physiology, but as seekers after evidence in their crusade against animal experimentation of any kind. They were well educated and might be supposed to be honest. It would be natural, therefore, to believe that they could see and understand what went on within a few feet of them, and would take pains to report truthfully what they saw. They testified that they saw no tube connection made for purposes of artificial respiration; that the animal experimented upon made many purposive movements, indicating a conscious struggling; that they smelled no anesthetic, and believed that none was given; that cries, whines, and barks had been heard, and that the animal had made a shrinking movement, as of fear, at the first approach of the operator. As against this professedly close and accurate observation, it was proved in court, before the Lord Chief Justice of England: (1) that artificial respiration was carried on all the time the animal was on the

table in front of them; (2) that the animal was profoundly anesthetized — one and a half grains of morphia (a very large dose) had been injected before it had been brought into the room and that six ounces of the "A. C. E." mixture (alcohol, chloroform and ether) had been used during the operation; (3) that this particular dog was affected with chorea, and that the movements seen were choreic, not purposive, in character; (4) that tracheotomy had been performed, and it was impossible therefore that any cries, whines or barks could have been heard; (5) that the shrinking movement of fear testified to could not have occurred for the above reasons.

The ladies, relying upon their own powers of observation, made a statement of what they claimed to have seen to Mr. Stephen Coleridge, honorary secretary of the Anti-Vivisection Society (of England), a lawyer and a member of the English bar. This gentleman, as he testified, accepted their statement without any attempt at verification, although he knew that giving publicity to it would be likely to be followed by prosecution. Apparently, however, the search for evidence to support the agitation had grown so desperate that this opponent of animal experimentation was ready, even anxious, to use the testimony, and did so, amid great enthusiasm, at the annual meeting of the Anti-Vivisection Society, early in May, 1903.

The prosecution for libel followed promptly, with the substantial verdict against the defendant of nearly ten thousand dollars (£2000).

That a lawyer, trained in the weighing of evidence and with a knowledge of the necessary responsibility accompanying specific assertions of cruelty, should have taken no step to verify his supposed facts, seems inexplicable. The defendant gave as his reason that he knew they would be denied, and during cross-examination went so far as to say that he still beleived the women to have testified to the truth; this after their statements had all been denied under oath.

Here is the condition of mind we have found much nearer home. The opponents of animal experimentation deny its usefulness, in the face of overwhelming evidence to the contrary, evidence that to them is not such, for they do not believe it when it is stated, and take no pains to verify it by actual observation. It may, perhaps, be fortunate, after all, that such attempts at verification are not made by such people, if their interpretation of the facts seen by them is to be as false as it was in this instance.

It has not yet happened that specific allegations of cruelty have been made in Massachusetts. Of general assertions there have been many, all of the same character, and repeated year after year. Perhaps such a disastrous failure as that of Mr. Coleridge, in the exploitation of an unsubstantiated calumny, may prove a salutary warning even to the most violent opponents of physiological research and teaching. That simple limitation is not what they desire, but absolute prohibition, is becoming more and more evident year after year.

If the unhampered advance of medical knowledge is to go on, ever watchful care must be taken that methods like those illustrated in this trial are not successful. (H. C. Ernst, editorial, *Journal of the Massachusetts Association of Boards of Health*, xiv, No. 1, Feb., 1904.)

This case furnishes the best possible example of the difficulty of relying upon the observation of persons whose honesty of purpose may hardly be questioned, as one was not at first tempted to do, even in this instance. What, however, can be said, when, in spite of the testimony brought out in the trial of the suit for damages, showing that their observed and deduced facts were not facts; in spite of the advice of the defendant in this suit, whose reputation and pocket had suffered so severely by reason of his reliance upon their statements, — what can be said of the honesty of purpose that led these women to publish this same case as truth, and without a single qualifying word of doubt? Such methods of interpretation are not a surprise to one like myself, whose duty has required the close examination and sifting of assertions brought forward in support of repeated attempts to secure unnecessary and burdensome legislation upon this subject in this Commonwealth.

I have, I believe, been more or less actively concerned in opposition to every attempt at legislation of this sort in this state. I do not remember that I have missed a single hearing upon the matter; and I have attempted to sift every piece of assertion that has been brought forward in favor of the proposed legislation to further restrict or to abolish animal experimentation. I paid so much attention to the matter in the early days of my experience with it because I wanted to learn. I am myself a lover of animals, as all my neighbors know; and when my own work began to lie in the direction of animal experimentation in the hope of increasing the sum of human knowledge or doing some small thing towards the relief of human suffering, it became a matter of anxious consideration with me as to how much of this work I should do and how far such influence as I had should be allowed to support it.

So far as I have been able to do so, I have studied the matter from all its points of view, from its moral as well as its utilitarian side; and so far as its justification is concerned, the evidence has appeared to me to be so overwhelmingly in its favor that I have been compelled to become its uncompromising supporter. It seems to me impossible that anyone who has lived, as it is our privilege to live, in a generation that has seen the labors of a Pasteur, of a Koch, or of a Reed; who has had actual experience in seeing the sick snatched from the grave by the timely use of the results of similar labors; or who is able to realize the enormous saving of life to both man and the lower animals as the result of this method of study; it seems, I say, impossible that such an one can honestly oppose the continuation of the practice of animal experimentation in the freest possible way.

And by this I do not mean, nor do I know anyone else to mean, unlimited freedom to anyone to experiment at any time and in any way upon the lower animals. Such freedom does not and should not exist.

That it does not exist is not, I believe, generally known, for it is only because the present laws in the case are not known that much of the support is given to the annual agitation for further restriction of the practice. One example of this is furnished by a well-known and highly honored clergyman of this community, who signed the petition for one of the recent bills and appeared at a hearing in its favor. At this hearing he spoke eloquently and somewhat at length in favor of placing some restrictions upon the practice, evidently under the impression that none then existed. Upon being informed of the actual condition of the laws and that the passage of the bill would seriously interfere with the beneficent work of many of his friends, his consternation was amusing, and pathetic as well. He himself proposed the remedy that the remonstrants to the bill should get up a counter petition, and promised to sign that, too.

It is not true that restrictions to the practice of animal experimentation are lacking. The implications and assertions that none exist are not based upon facts, any more than is the description already quoted, of what "vivisection" is.

The editorial writer in *The Outlook* speaks of the needlessness of such demonstrations in the public schools, and in that I heartily agree with him. But there is now, and has been for years, a law upon the statute books absolutely prohibiting vivisection in the public schools, and no attempt whatever has been made, so far as I have heard, to modify or to evade its provisions. This part of the question is therefore absolutely closed.

The present laws governing cruelty to animals cover all remaining cases, and to show how completely this is true I may be permitted to quote them in part: "Whoever overloads, overdrives, or overworks, or deprives of necessary sustenance, or cruelly beats or mutilates an animal, or procures this to be done to any animal; or, having charge of or being in custody of any animal, inflicts unnecessary cruelty upon it, etc., is punishable by imprisonment in a jail for a period not exceeding one year, or by a fine not exceeding two hundred and fifty dollars, or both. A corporation which violates this provision is punishable by fine and is responsible for the knowledge and acts of its agents or servants. Officers are authorized to arrest without a warrant persons who are suspected of being guilty of this act." And finally, there is a most stringent and unusual provision to the effect that when a complaint is made to a court or magistrate and when the complainant believes, and has reasonable cause for believing, that this law is being violated in any particular building or place, and the magistrate or court is satisfied that there is reasonable cause, he may issue a search warrant to search the building." (Adapted. Public statutes, Chap. 297, par. 52.) First rate legal opinion comments as follows: There is, therefore, in Massachusetts, a law applicable to vivisection of the most extreme kind, which would enable any person who could satisfy a court that he has reasonable cause to suspect that cruelty was being practiced in a Massachusetts medical school, or elsewhere, to procure a search warrant to search the premises and discover the animal and the parties cruelly treating it, and to cause the arrest without a warrant of the persons who are suspected of practicing the cruelty. So that this agitation is directed, as, indeed, has many times been acknowledged, against the professional schools, for vivisection is not practiced in any other schools in this commonwealth.

This being so, the question at once arises as to the trustworthy character of the trustees of our educational institutions on the one hand; whether they are so negligent of the duties entrusted to them as to allow such fiendish cruelty to go on as is asserted to occur; and on the other hand, whether the instructors appointed by them, after searching inquiry as to character as well as training, are so callous and unfeeling as the accusations state. In all the years that the hearings have occurred at the Massachusetts State House no evidence has been brought forward proving the existence of such a state of affairs. It may justly, therefore, be supposed that the public confidence in these officials is not misplaced.

Much of the argument against animal experimentation, of late years, has rested upon assertions and implications that the experiments are conducted without anesthetics efficiently used, and while the animal is conscious and suffering. Assertions of this nature, like the description of vivisection already quoted, are absolute, and as I believe, intentional falsehoods. So far as my personal work is concerned or that of the laboratory under my charge, I may say that no experiment, except simple inoculations, has ever been made except under profound anesthesia. I have never seen one done, and I know them to be of the rarest occurrence, only considered at all, when the object to be gained can be reached in no other way.

In other words, the demand that such operations be conducted with all possible precautions to avoid unnecessary suffering is already met, in every institution of which I have personal knowledge or which has been brought to my notice.

I have said publicly many times that if evidence is presented to me or my friends in this matter demonstrating the existence of abuses that the present laws do not fully cover, we will support an active movement for reform. We must have evidence of worth, however. One can hardly be expected to ask for new legislation upon the testimony of an agitated lady near our medical school, who was much troubled by the daily current of beautiful collie dogs taken in every morning — and never coming out again. These were my dogs, who used to run in with me every morning as I rode or drove through the

park, and who never seemed to go out again, because, being the fall, we all went home after dark. I believe it to be possible to assert with truth that the requirements of careful supervision and a minimum of suffering are fulfilled in every institution where the practice of animal experimentation is carried on. Certainly, if this is not so, it is strange that I have never heard of any proof of the existence of the abuse of the power of man over animals in this direction that has not been promptly rebuked. If such abuses do exist there is plenty of law on the statute books to secure their punishment, and it would be my duty and pleasure to take part in the enforcement of these laws.

The Society for the Prevention of Cruelty to Animals finds no difficulty in securing convictions under the present laws in cases of abuse brought to its notice.

The complaint often made is that it is difficult to secure evidence of the abuse of the practice of animal experimentation, because those desiring to secure such evidence cannot get in to the laboratories or demonstration rooms where experimentation is going on.

That the desire of any intelligent person for information on this subject or for admission to any laboratory where this practice goes on has ever been denied, I do not believe. It certainly has not been so in any place with which I am familiar. On the contrary, it is the fact that some of the most prominent agitators against animal experimentation have refused direct invitations to come and see for themselves, and one in particular is on record with the remarkable assertion, "I do not need to go into a laboratory to know what is going on there."

The whole case may be summed up thus: if man's dominion over other animals is justifiable at all, then the use of those animals for the furtherance of his and their well-being is justifiable in the direction of experimentation, as in others. Such use must, however, be surrounded by all safeguards that it shall be merciful and as painless as possible. Such safeguards, those competent to judge have said again and again, are in existence, and no proof to the contrary has been brought forward.

Original Articles.

A STUDY OF AMPUTATIONS OF THE LOWER EXTREMITY.

BY FRED T. MURPHY, M.D. BOSTON.
For the Division of Surgery of the Medical School of Harvard University.

Amputations of the lower extremity, as a class, offer little of technical interest to the operator. They are usually traumatic cases of such extent that the saving of the patient's life is the main question. The operator is apt to consider the immediate result, while to the patient the ultimate usefulness of the stump is of major importance. Generally speaking, a good immediate result means a good end result, but in amputations this may be far from the truth.

When artificial appliances were in the crude state, the principle was taught, "save as much as you can," and to a remarkable degree such is the opinion held at the present day. Observations of numerous failures to obtain a serviceable stump by following this teaching suggested to me the investigation of the relative values of the various methods of amputation of the lower extremity as regards the production of a useful stump.

Through the courtesy of the staff of the Massachusetts General Hospital the hospital records were placed at my disposal, and Dr. J. Collins Warren kindly allowed the use of his name in correspondence with the patients and with the manufacturers of artificial limbs, for both of which favors I am deeply indebted.

Data were obtained from three sources, namely: the hospital records, the patients and the makers of artificial limbs.

In order to get an idea of the type of cases and the immediate results, that is, the results before leaving the hospital, the records of five hundred cases were abstracted. These cases were taken as nearly as possible in consecutive order and include the years from 1889 to 1901 and part of 1888 and 1902, but owing to the irregularity of the diagnoses it was not possible to depend upon the card catalogue, and certain few cases may have been overlooked in going through the individual record books.

The following list of questions was sent to each of these patients who had left the hospital alive, with a note asking them to answer the questions and return them to me in case they were not able to come to the hospital for examination:

"Do you wear an artificial limb? If not, why? How long after the operation was it before the tenderness would allow one to be worn? Can you walk without crutch or cane? Can you do any manual labor? What? Do you ever have pain in the stump? Is the pain localized in the end of the stump? Does the leg draw up with cramps? Has there been any sensation as if the toes were cramped? If so, how long before this sensation wore away? Has the weather any effect on the stump? Does the stump ever swell or discharge? Does the artificial limb cause pain or discomfort? Have you had any operation since the first amputation? Who made the artificial limb? What did it cost? How often has it been necessary to have the limb repaired? About what has been the cost of such repairs? After your experience, what suggestions would you make regarding the treatment of an amputation such as you have had?"

Recognizing the wide experience and ability of the best makers of artificial limbs, another list of questions was sent to eleven of the well-known firms of the East and West. These gentlemen have been more than courteous in their efforts to help me, both by replying by letter and pamphlet and by calling in person. I take this occasion to thank them, and to urge a closer coöperation

between the surgeon and the prosthetician, for it is by this means that the problem will be worked out and the best results given to the patients.

The following table shows the class of cases and the mortality in the hospital:

TABLE OF AMPUTATIONS.

	Total.	Died.
For crush:		
(Single)		
Thigh	66	27
Leg	172	8
Partial foot	32	1
(Double)		
Thigh	1	
Thigh and tibia	11	2
Thigh and partial	1	
Tibia	19	6
Tibia and partial	5	1
Partial	1	
For bad stumps of		
Thigh	11	
Leg	35	1
Partial	6	
For sepsis:		
Thigh	11	4
Leg	4	1
For gangrene:		
Thigh	31	11
Thigh and leg	1	1
Leg	23	12
Partial (double)	1	
For new growth:		
Double thigh	1	1
Thigh	32	5
Leg	12	2
For tuberculosis and osteomyelitis:		
Thigh	17	1
Leg	6	
Partial	1	
	500	84

The general and local conditions in individual cases exerted such an influence upon the result and upon the technic of the operation that statistical comparisons, either as to the immediate results or the mortality, would be impossible and unfair. But certain facts were boldly emphasized. As might be expected, the amputations for new growth did much better, as far as the healing of the stump was concerned, than those done for trauma and gangrene. In general, the immediate results of all the amputations as compared with the perfect healing seen in other classes of clean cases, were most disappointing. Union by first intention was the marked exception rather than the rule. Ordinarily in clean cases three weeks may be taken as a surgical unit of time which represents by a slight addition or subtraction the time of convalescence, but in these amputations it would be hard to fix a limit of time, so persistent were the indolent granulations and sinuses. In many instances the use of bruised tissue for emergency flaps was necessary, and in these cases the failure to obtain satisfactory healing was to be expected, but not infrequently the poor result seemed to be due to the technic rather than to the unavoidable conditions. These failures, with few exceptions, were due to the infection of the clot of blood and serum which had collected beneath the flaps or were caused by the failure to provide a suitable covering for the end of the bone. The skin flap with a circular incision was the one most often used, and it seems to me the least desirable, except in such regions as the lower third of the leg and when demanded by necessity. Certainly, the muscle flaps in the thigh and the upper part of the leg gave much more favorable results than when the skin alone was used.

Unless the soft parts were carefully approximated and held by buried sutures, the drained cases did noticeably better than when the attempt was made to obtain a complete first intention. These attempts not infrequently led to the following sequence: first intention of the skin, about the fourth to sixth day, expression of the blood clot by opening the line of incision, infection causing a sinus or further opening of the incision to pack the cavity, retraction of the flap sometimes resulting in protrusion of the bone followed by reamputation or skin-graft. Where muscle flaps were obtainable, the method of suturing the periosteum over the end of the bone and approximating the muscles and fasciæ by buried or mattrass sutures gave excellent results. There were no instances of osteoplastic flaps except in amputations at the ankle-joint. As a routine, the cases were operated as soon as it was possible to obtain a surgeon, so that no statement can be made as to the relative value of immediate or delayed operation in the traumatic cases. Judging from the records, the shock of amputation *per se* below the upper third of the thigh was not marked.

Except for the question of flaps and drainage, the immediate results of the routine leg and thigh cases have no special interest in connection with this paper. A class of amputations, such as the so-called Syme's, Pirogoff's, Chopart's, Lisfranc's, Hey's, etc., with their modifications, does, however, illustrate certain points which it will be well to bear in mind in considering the ultimate utility of these operations.

There were 44 operations of this class in which the immediate results could be judged. They included 12 tarso-metatarsal amputations, 3 of which were followed by reamputation; 17 mediotarsal amputations with 4 reamputations, and with 1 case which had not healed at the end of nine months and another which went on crutches for eleven months; 7 disarticulations at the ankle-joint, of which 1 was advised to have a reamputation, and another in which sinuses persisted; 8 Pirogoff's with 1 reamputation and 3 cases with faulty position of the fragment of the os calcis. In addition to these more marked failures, these amputations of the foot were generally slow to heal.

Failure to obtain a good result in about 33⅓% is significant.

The opinions of the makers of artificial limbs were in the main remarkably unanimous. Regarding minor details there were differences, and

rarely the position was taken that any stump could be satisfactorily fitted.

In the following comments I have endeavored to express the prevailing idea and that which seems to me to be the most reasonable.

Here, as was the case in considering the immediate results, exceptions may be cited to disprove any statement, but in general, that is, to obtain the greatest benefit to the greatest number, the experience of the makers of artificial limbs supports the following conclusions:

The Lisfranc's, Hey's, and Chopart's and the irregular midtarsal amputations were considered in a single class. The preservation of the attachment of the *tibialis anticus* gives a theoretical advantage to Lisfranc, but practically it is open to the same objections as the others, namely: a weak supporting arch and a tendency to extension of the stump even though the Achilles tendon be divided. Given an ample flap which assures the placing of the scar on the dorsum of the foot so that it will not be irritated by pressure, and a perfect result without extension of the stump, it was held by the makers that these operations were acceptable, but so rarely was this perfect result seen that generally such amputations were condemned. Even under the most favorable conditions, it was questioned whether these amputations gave as strong a supporting leg as a tibial stump. Any appliance, other than a simple cosmetic false foot which offers little or no support, is cumbersome and difficult to fit with comfort to the patient.

Operations of the type of the Syme and the Pirogoff formed the next group to be considered, and they, too, were disapproved. The Syme, or the modification with the lateral flap when perfect, offers simply a peg leg. Displacement of the heel pad so as to bring the cicatrix into bad position had been the general experience. The bone flap of the Pirogoff increases the length of the leg, and with a perfect result makes a smoother stump. Malposition, however, of the bony fragment or of the cicatrix had been the rule. The greatest difficulty had been found in providing a satisfactory apparatus after these operations.

Going above the ankle-joint the opinion was ananimous that the long stumps obtained in amputations through the lower third of the leg were undesirable. Different levels were suggested, varying between the middle of the middle third to the junction of the middle and lower thirds. In inches, lengths between 6 and 10 inches measured from the lower border of the patella were acceptable. The longer stumps have been found to show a tendency to swell at the end, and the greater leverage without material gain in handling the foot increased the liability of play in the socket, thus causing irritation of the anterior border of the tibia. A stump shorter than six inches has been found to decrease the usefulness of the leg by lessening the power of leverage. A tibial stump two inches long was accepted as the minimum which would give a satisfactory bearing for an artificial leg which would preserve the function of the natural knee joint. Amputations necessitating a shorter tibial stump opened the question of sacrificing the knee. The old operation of saving the short tibial stump gives with flexion a good, serviceable, end-bearing but cumbersome leg. As in amputations through the joint, it necessitates a bulky apparatus and in the sitting posture makes one thigh longer than the other. Amputations through the joint were generally considered to possess no advantage over those above the condyles, and to have beside the disadvantage of necessitating a clumsy apparatus and to be liable to irritation over the bony prominences.

Gritti's procedure of placing the patella at the end of the femur was not advised. When successful the end bearing is good, but the bone is apt to be displaced, and even the perfect result is open to the same objections as the other knee joint operations.

Above the knee it was advised that the stump be left as long as possible, provided the condyles of the femur be removed. Measured from the perineal fold, any thigh stump longer than five inches was considered to be satisfactory and useful. Stress was laid on the importance of obtaining a good, not redundant, end pad; the necessity of beveling the bony prominences, such as the anterior border of the tibia, and careful resection after traction of the nerves was emphasized.

In the short leg amputations it was suggested by some that the fibula should be sub-periosteally resected, and in all cases that it be cut off at a higher level than the tibia. "End bearing" was considered as desirable but not at all as an essential.

One hundred and sixteen of these patients were seen and personally examined or followed by letter. Results are considered as "fine" when the patient is able to walk without a cane and to do ordinary manual labor, as "good" when able to walk with a cane or with slight discomfort and to do light work.

In this series there were 35 cases of amputation of the thigh. Seven died without using artificial limbs to any extent, four from sarcoma, two from tuberculosis and one from gangrene. Five have not tried to use artificial limbs, either because the leg could not be obtained or because they are too comfortable on crutches. Nine are "fine" results and are able to do practically the same work as before the injury. Nine cases are classified as "good" results. Three are bad, two being in old men so weak that the uninjured leg will not bear the weight of the body, and one a conical stump in a child who was operated at four years of age. One patient has new bone reforming in the stump after an excision at the hip joint and will ultimately be able to wear an artificial leg. Another has a fine stump without evidence of neuromata or irritation, but thus far has not been able, on account of pain, to use an artificial leg. From these cases no special conclusions could be drawn. Where muscle flaps had been taken, the covering at the end of the

stump seemed much more fitted to stand rough usage than where the skin alone had been used.

Sixty-one cases of leg amputation were followed. Six have died, one of whom, at the time of death, would be classed as a "good" result. Six as yet have no artificial legs, four of whom are waiting to be fitted, one had sloughing of the flaps and the bone still irritates the skin, and one is an old man with a tender adherent flap. Forty are "fine" results and nine are classified as "good."

These tibial amputations illustrated most graphically the suggestions made by the prosthetic ians. The most perfect results were seen in the shorter tibial stumps, that is, about six inches. The long stumps from amputations of the lower third, almost without exception, caused trouble by swelling and from the irritation on the anterior edge of the tibia. Several cases were seen where the too long fibula caused marked tenderness in the end of the stump. The extra leverage above six inches gave no advantage. The shortest tibial stump observed was two and one-half inches with which the patient was able to do active and hard manual labor. On the whole the slight amount of disability caused by the loss of a foot was remarkable. The claim sometimes advanced by manufacturers that shoulder straps for support of the leg are not necessary was not borne out by these cases, as their use was almost universal.

The ten cases of double amputation are tabulated in order that a comparison between the stumps may be more readily seen:

Pirogoff — painful.
Partial — fine.

Pirogoff — fine; patient would much prefer a tibial stump.
Tibia, 4 inch, much the stronger leg.

Chopart — good, but patient wishes it were a tibial amputation.
Middle third of tibia, fine, much the stronger leg.

Tibia, 10 inch, fine.
Tibia, 2.5 inch, fine.

Tibia, 7 inch, fine.
Tibia, 8 inch, fine.

Tibia, 7 inch, fine, considerably the stronger leg.
Tibia, 9 inch, fine.

Tibia, 4.5 inch, fine, much the stronger leg.
Tibia, 10 inch, fine.

Thigh above condyles, fine.
Mid-tibia, fine.

Partial foot, fine.
Middle and lower third tibia, fine.

Mid-thigh, good.
Mid-tibia, good.

With the exception of the last case, who has been fitted with the artificial legs only a short time, these patients with a double amputation have experienced remarkably little discomfort. There are included laborers who do hard work and youngsters who go to school and play ball.

The partial amputations of the foot and those at the ankle-joint are also given in tabulated form:

Syme's, fine.
Syme's, fine.
Syme's, good, but patient would much prefer a short tibial stump.
Syme's, good, but there is bad displacement of heel pad and scar, and patient wants a reamputation.
Syme's (lateral flap), good, but patient would prefer a tibial stump.
Lisfranc's, good, but considerable pain.
Chopart's, fine; walks well but not so strong as a good tibial amputation.
Chopart's, fine.
Chopart's, good, but with apparatus makes a clumsy foot.
Chopart's, fine, but not satisfactory with artificial limb.

A failure of 33⅓% in the immediate results and the unsatisfactory end results must, it seems to me, condemn all of the partial amputations of the foot or at the ankle-joint.

The summary of the replies to the questions which have not been considered in the preceding paragraphs is as follows:

Simple tenderness in the stump prevented the wearing of an artificial limb for from two months to two years. In the majority of cases the stump was ready for the leg in from five to seven months. Intervals of slight pain in the stump was the rule. The pain was rarely localized in the end of the stump, but was referred to the foot. The leg itself was universally reported as being free from cramps, but the absent toes almost as generally were subject to periods of more or less severe discomfort. To a very slight degree the sensation in the toes persisted, usually growing markedly less after about the first year. Opinions regarding the influence of the weather were most variable. In some, extreme cold caused discomfort, while in others heat was to be dreaded, and still another group felt a storm or an east wind. This discomfort, which was experienced by about one third of the patients, was apparently no more severe than is found in the average individual with a "rheumatic tendency." Only in the long tibial stumps or with improperly fitted sockets was there marked swelling or discharge from the stump. Any artificial appliance must of necessity cause some discomfort, but generally speaking the limbs were worn with remarkable ease. Twenty-four cases had undergone some secondary operation after leaving the hospital. Incompleteness in the replies prevents a definite statement regarding the exact character of these operations, but usually they had been of a trivial nature, such as the opening of an abscess or the removal of necrotic bone or neuromata. As "suggestions," nearly all of the patients confined their remarks to the after treatment of the stump. They complained, as did the makers of artificial limbs, that usually no directions were given on leaving the hospital as regards bandaging the stump. If left alone, the soft tissues hypertrophy and become flabby, necessitating later the wearing of a "shrinker" before a socket can be fitted. In order to prevent this the stump should be bathed frequently,

FIG. 1. Disarticulation at ankle-joint. Shows the displacement of the heel-pad "A" and the tender point "B" on the anterior edge of the tibia.

FIG. 3. Pirogoff and 4-inch tibial stump. The short tibial stump is the more useful.

FIG. 2. Tibial stumps, 10 inches and 4½ inches in length. The shorter stump is the more useful.

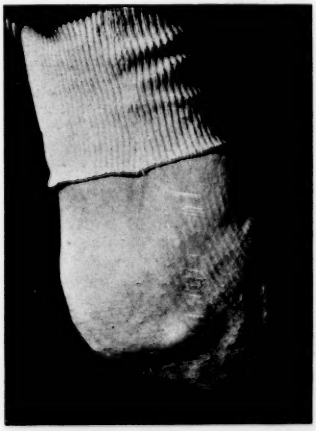

FIG. 4. To show how short a tibial stump can be and yet afford perfect function.

NOTE.—The writer is indebted to Mr. Walter J. Dodd of the Massachusetts General Hospital for the illustrations used in this paper.

FIG. 5. Six-inch tibial stump. Good free end pad. No discomfort. Perfect function. Patient weighs 206 pounds.

FIG. 6. Bad conical stump of thigh.

FIG. 7. X-ray of stump of a tibial amputation, showing bony change caused by constant irritation of the anterior edge of the tibia; also illustrates the common error of leaving the fibula too long.

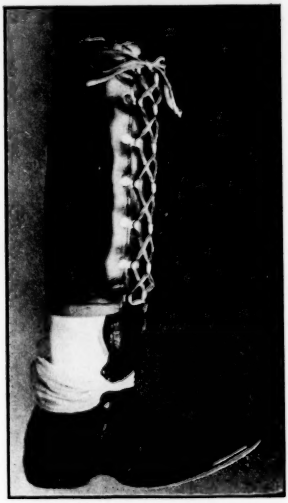

FIG. 8. Cumbersome apparatus seen on Syme's amputation. Compare with Fig. 9.

FIG. 9. Ordinary artificial leg for tibial amputation. For comparison with Fig. 8.

either with cold water or some mild astringent solution, and kept bandaged with flannel under moderate tension so that there will be slight compression, or should be encased in a proper leather support. The cost of the limbs was from $50 to $100. With ordinary use and with a good make of leg, repairs were necessary once or twice a year. Their cost was, as a rule, insignificant. Often the repairs were made by the wearers themselves.

It is not the purpose of this paper to attempt to consider the merits or faults of the various styles and makes of artificial legs, but if it were, I should have great difficulty in condemning wholly any one type. Given a first-class artificial limb, whatever the make may be, and an intelligent patient with a satisfactory stump, and the functional result will be remarkably good. Failure on the part of the patient to practice a proper gait and to endeavor to correct the faults is, it seems to me, more often to blame than is the artificial leg.

The conclusions warranted by these observations are as follows:

Anterior and posterior muscle flaps when obtainable are to be preferred to the circular cuff of skin.

The fibula should be cut off at a higher level than the tibia in leg amputations, and care should be taken to bevel off bony prominences such as the sharp anterior tibial edge.

Suture of the periosteum and approximation of the muscles and fasciæ is desirable.

Drainage of the stump is advised, unless the dead space is obliterated by means of buried sutures.

Partial amputations of the foot or amputations at the ankle-joint, except under unusual conditions, are not as satisfactory as those above the ankle-joint.

Tibial stumps between 6 and 8 inches long are the most serviceable.

Amputations through the knee-joint are inferior to those just above the condyles.

The longer the thigh stump the better, provided the condyles have been removed.

In general, in tibial amputations down to 4 inches and in thigh amputations down to 5 inches, sacrifice bone in order to obtain good muscle flaps.

EXPERIMENTAL DECAPSULATION OF THE KIDNEYS.

BY N. H. GIFFORD, M.D., BOSTON.
From the Laboratory of Surgical Pathology. For the Division of Surgery of the Medical School of Harvard University.

THIS article contains the results of a year's work on the experimental decapsulation of kidneys, performed on animals in the surgical laboratory of the Harvard Medical School, aided by the suggestions of Dr. E. H. Nichols.

Dr. H. A. Johnson, in the *Annals of Surgery* for April, 1903, and Albarran and Bernard, in the Société de Biologie in June, 1902, have published papers bearing on the first part of my work, that of the rabbit series. As my results differ in many respects and there are some additional observations, I take the liberty of presenting this paper.

The experiments have been conducted upon rabbits and dogs.

In each rabbit or dog I have decapsulated one kidney, always the left because it is normally smaller than the right by one fourth to one third and lies more inferiorly, thus giving greater ease of access from lumbar incision. The animals were etherized, the hair clipped, the remaining hair removed by sulphur paste, and the operation performed, as far as possible, under aseptic precautions. In no case, either in rabbits or dogs, have I found the peritoneum so closely adherent over the capsule of the kidney as to be torn in the delivery of the kidney into the wound for decapsulation. After delivery of the kidney the capsule was split along the greater curvature from pole to pole, stripped off by the help of forceps, if necessary, and the kidney returned to its original position in the retro-peritoneal fat. The wound was then closed with deep interrupted, heavy silk sutures, and the animal returned to the pen to be killed after an allotted time had elapsed. The animals were killed by the injection into the lung of from one-eighth to one-fourth grain strychnine sulphate.

The specimen was preserved immediately after removal in Zenker's fluid, by placing the kidney in the fluid, intact, for one hour, and then cross-sectioning into slices, two to four mm. thick. This method prevents slipping or tearing away of the capsule by the knife, as is true in making fresh sections. In all cases the unoperated kidneys were removed at autopsy and preserved in the same manner to be examined as controls.

The rabbit series comprises two, four, six, eight, ten, and thirty-one days and six months after operations.

TWO DAYS: The left kidney, by measurement, is one-third larger than the right. There is a thin layer of blood clot about the kidney.

Microscopically. — In places about and external to the cortex few very young connective tissue cells appear. There are no connective tissue fibrils by Mallory's connective tissue stain. There is moderate congestion of all the vessels and capillaries in the kidney substance. No change in renal epithelium appears.

Microscopically. — The right kidney shows a capsule two to four cells thick.

FOUR DAYS: The left kidney is one-fourth larger than the right. Thin, fibrinous adhesions with little blood clot appear about kidneys.

Microscopically. — A layer of new connective tissue cells appears on the cortex, five to seven cells thick, showing by Mallory's connective tissue stain a few connective tissue fibrils. There are new blood vessels from the cortex and a slight infiltration with polynuclear leucocytes, plasma cells and eosinophiles. The capillaries of the outer cortical zone show slight injection. There is no change in the renal epithelium.

Microscopically. — The right kidney shows a capsule two to four cells thick.

SIX DAYS: The left kidney is one-fourth larger than the right. The blood clot has disappeared. The kidney is rather firmly imbedded.

Microscopically. — There is no injection of the vessels of the kidney substance. A new capsule appears about the kidney, ten to twenty cells thick, rather rich in blood vessels, showing by Mallory's connective tissue stain numerous medium long, well-formed intercellular fibrils. The cells of the outer layer of the new capsule are rich in yellow pigment. There is no change in renal epithelium.

Microscopically. — The right kidney shows a capsule three to five cells thick.

EIGHT DAYS: The left kidney is one-fifth to one-fourth larger than the right. There is no blood clot.

Microscopically. — No injection of the vessels appears. There is a new capsule of connective tissue ten to fifteen cells thick, rather rich in connective tissue fibrils and blood vessels. There is no change in the renal epithelium.

Microscopically. — The right kidney shows a capsule two to five cells thick.

TEN DAYS: The left kidney is one-fourth larger than the right and is firmly anchored. There is no blood clot.

Microscopically. — A new capsule, rather rich in connective tissue fibrils and blood vessels, appears, ten to fifteen cells thick. There is no injection. There is no change in the renal epithelium.

Microscopically. — The right kidney shows a capsule two to four cells thick.

THIRTY-ONE DAYS: The left kidney is slightly larger than the right, and is firmly anchored.

Microscopically. — The vessels are not injected. A new capsule appears, seven to fifteen cells deep, with long connective tissue fibrils in abundance, and a few new blood vessels. There is no change in the renal epithelium.

Microscopically. — The right kidney shows a capsule two to four cells thick.

SIX MONTHS: The left kidney is approximately the same size as the right. The capsule of the left kidney shows a few spots two to three mm. in diameter, yellowish and opaque but not appreciably thick to touch. The remainder of the capsule is transparent like that of the right kidney.

Microscopically. — There is a capsule of connective tissue two to four cells deep, with a few long, connective tissue fibrils closely packed and rather sparsely supplied with blood vessels. Sections through the opaque areas show a capsule four to eight cells deep. Except these slightly thickened areas, whole section of left kidney not different from that of right whose capsule is from two to four cells deep. No change in renal epithelium.

From the above we see that as early as the second day after the operation new connective tissue cells begin to appear in the clot about the decapsulated kidney. On the fourth day connective tissue fibrils begin to be formed, and by the tenth day a new capsule, rich in blood vessels and three to four times normal thickness, surrounds the kidney. That the capsule has been entirely removed by the operation shows in the two-day specimen and also in the three controls which I made, after seeing the article by Johnson in which he claims the impossibility of entirely removing the inner capsule. In the kidney substance there is a rather well marked intertubular congestion up to the fourth or fifth day, but no change in the cells of the blood vessel walls is observed at any time. The tubules and glomeruli remain unchanged.

In the operation when the capsule is split, it immediately draws back and the kidney pops out as if under tension. This is probably due to the congestion caused by putting the renal vessels on stretch and thus narrowing their caliber. This would have more effect on the veins because of their relatively thinner walls. This increase in size, however, persists.

The operated kidneys, as can be seen by the above, are increased in size up to thirty-one days afterwards. At the end of six months, however, they return again to nearly normal size, and at the same time the capsule is but little thicker than normal.

In the dog series sections were made three, eight, and fifteen days after operation on normal animals.

THREE DAYS: The left kidney is one-fourth larger than the right. There is considerable blood clot in the perirenal tissues but the kidney is held fairly well in place.

Microscopically. — There is moderate injection of the subcapsular vessels. There appears a capsule composed of young connective tissue cells, fifteen to twenty-five cells deep, with few rather short connective tissue fibrils and rather rich in new blood vessels. Both the left and right kidneys show areas in cortex of slight increase of connective tissue, including atrophied glomeruli and a few infiltrating lymphoid and plasma cells. There is no change of the renal epithelium.

Microscopically. — The right kidney shows a capsule six to twelve cells thick.

EIGHT DAYS: The left kidney is one-fourth larger than the right. Very little blood clot appears in the neighborhood. The kidney is firmly anchored.

Microscopically. — No injection of vessels appears. The capsule is composed of new connective tissue, ten to twenty cells thick, with medium long, wavy, connective tissue fibrils, and rather rich in newly formed blood vessels. There is no change in the renal epithelium.

Microscopically. — The right kidney shows a capsule six to twelve cells thick.

FIFTEEN DAYS: The left kidney is one-sixth larger than the right.

Microscopically. — There is no injection of the vessels. A new capsule is present composed of connective tissue with a few blood vessels, fifteen to twenty-five cells thick, and with quite num-

erous connective tissue fibrils. The new connective tissue of the capsule connects in places with some new connective tissue, running a short distance into cortex between the tubules. There is no change in the renal epithelium.

Microscopically. — The right kidney shows a capsule seven to fifteen cells thick.

Acting upon the idea that while no definite histological changes might follow the decapsulation of kidneys of normal animals, decapsulation of kidneys showing existing pathological changes might give more fortunate results, in that the conditions present were like those in the clinical cases which have been so successful — I next tried to induce nephritis. I chose nephrolytic serum as the best means of inducing nephritis. The nephrolytic serum was obtained by injecting an emulsion of washed dog's kidney subcutaneously into rabbits at three-day intervals, and at the end of two weeks the rabbits were bled and the serum injected into apparently healthy dogs.

Eight hours: A dog was injected with 0.5 cc. nephrolytic serum. No symptoms resulted. Six days later 2.0 cc. of nephrolytic serum were injected with no symptoms immediately following. On the fifth day after the second injection the dog was reported in convulsions and coma (with diarrhea and vomiting and anuria). Ether was administered and the left kidney decapsulated through the lumbar incision. A wedge-shaped piece of the cortex was removed for examination. After coming out of ether the convulsions and coma persisted, the convulsions becoming more frequent and the dog weaker, until he died eight hours after the conclusion of the operation. Autopsy revealed no gross lesions other than congestion of all the organs.

Microscopically. — The piece removed from the left kidney at the operation shows swelling of the tubular epithelium, with obliteration of the lumen and separation from the basement membrane.

Microscopically. — The decapsulated left kidney shows the capsule is removed completely from two thirds of the surface, being replaced by blood clot. There is marked injection of the intertubular vessels and the larger vessels of the pyramids. The epithelium of the parenchyma is swollen, with solid staining or absent nuclei, and everywhere is torn from the basement membrane. There is no increase of the intertubular connective tissue.

Microscopically. — The right kidney shows a capsule six to ten cells thick. There is less injection than in the left, but the remaining lesions are essentially the same. (Acute Desquamative Nephritis.)

Microscopically. — The rest of the organs show nothing abnormal, except marked injection of the vessels and small areas of hemorrhage into the spleen and the lungs.

Two days: April 29, 1903. Dog injected with 0.5 cc. nephrolytic serum.

May 11, 1903. No symptoms. 0.5 cc. nephrolytic serum injected.

June 11, 1903. No symptoms. 1.0 cc. nephrolytic serum injected.

June 19, 1903. No symptoms. 0.5 cc. nephrolytic serum injected.

July 21, 1903. No symptoms. 1.0 cc. nephrolytic serum injected.

Sept. 24, 1903. The dog was reported sick, frothing at the mouth and in convulsions. One-half grain morphine sulphate was administered followed by ether and operation. The left kidney was decapsulated, and the right kidney removed through the lumbar incision. The dog appeared perfectly well following the operation with no more convulsions. At the end of forty-eight hours the dog was killed with three-eighths grain strychnine sulphate. The left kidney was one and one-half times as large as right, which had been removed at the time of the operation.

Microscopically. — The left kidney shows that the capsule has been entirely removed over half the convexity and is replaced by blood clot containing at all edges a few new connective tissue cells. At the edge of the denuded cortex are a few short, thick, wavy, connective tissue fibrils. In the cortex are areas of intertubular infiltration of transitional plasma cells, varying in size from that of a glomerulus to five or six times as large. These infiltrating cells are in active mitosis, and the glomeruli and tubules included are degenerating. There are a few areas of slight increase of connective tissue in the cortex, including atrophied glomeruli. The tubules appear rather widely separated, and the tubules themselves are dilated and contain circular reticulum.

Microscopically. — The right kidney shows a capsule three to five cells thick, rich in long, thin, closely packed, connective tissue fibrils. The description of the cortex is the same as in the operated left kidney above.

Diagnosis. — Acute non-suppurative interstitial nephritis.

Eight days: A dog was injected with 0.5 cc. nephrolytic serum. One month later the left kidney was decapsulated through the lumbar incision, and a wedge-shaped piece of the cortex removed for examination at the time of the operation. The dog was killed eight days after the operation.

Microscopically. — The piece of the left kidney removed at the time of operation shows capsule absent.

Microscopically. — The left kidney shows a capsule fifteen to thirty cells thick, composed of new connective tissue cells with long, thin fibrils between, and without are some areas of blood clot undergoing organization. The cortex shows no injection of the blood vessels. In the cortex are areas of lymphoid and plasma cell infiltration, slightly larger than the glomeruli, rather more numerous towards the medulla, and with slight increase of connective tissue in and about these areas. The glomeruli included show slight to marked atrophy with fibrous changes. There is no general increase of the intertubular connective tissue. The epithelium of the tubules is normal,

Microscopically. — The right kidney shows a capsule ten to fifteen cells thick. The cortex and medulla show the same condition as in the left.

I then produced kidney infarction in dogs in two cases, in one of which I decapsulated the kidney and in the other, I did not.

FOUR DAYS (unoperated): Through the abdominal incision the left renal artery and left ureter were tied off. The animal was killed four days later.

Microscopically. — The left kidney shows capsular and peri-capsular connective tissue, much thickened, containing fibrin, red blood globules, polymorphonuclear leucocytes and new connective tissue cells. The capsule is thirty to forty cells thick, with fairly short, thick, wavy, connective tissue fibrils, both in towards and into cortex and outside of original capsule. There is a moderate increase of the intertubular connective tissue in the outer zone of the cortex. The cortex itself shows the epithelium to be necrotic, with polymorphonuclear leucocytes within and without cells. In medulla are a few areas of apparently normal epithelium. The vessels are everywhere injected.

Microscopically. — The right kidney shows a capsule seven to twelve cells thick. The section of the kidney substance is in every respect normal.

SIX DAYS (operated): The left renal artery was tied off through the left abdominal incision and the kidney decapsulated. The animal was killed six days later. The left kidney was slightly smaller than the right.

Microscopically. — The left kidney shows a capsule twenty to thirty cells thick, composed of new connective tissue cells with medium, long, wavy, connective tissue fibrils in between them, and containing in their meshes numerous red blood globules. All the kidney substance, except one fourth about the hilus, is infarcted. Beneath the new capsule a few young connective tissue cells extend in about the intertubular vessels.

Microscopically. — The right kidney shows a capsule seven to ten cells thick. There is no increase of the intertubular connective tissue. The epithelium and glomeruli are normal.

Finally, I removed the left kidney from a dog, and five and one-half weeks later decapsulated the right through the lumbar incision. At the end of eight days the dog was killed. The right kidney at time of operation was one and one-half times size of the left, which had been removed.

Microscopically. — The right kidney shows a capsule ten to twenty cells thick, with new connective tissue cells and medium long, fairly thick and slightly wavy connective tissue fibrils. Fairly numerous blood vessels appear in it. The intertubular blood vessels and the connective tissue are unchanged. The glomeruli and tubular epithelium appear normal.

From the dog series I find that, after decapsulation of the kidneys of normal dogs, of dogs after nephrolytic serum with the nephritis apparently induced thereby, and after the decapsulation of infarcted kidneys of dogs, and of kidneys of dogs with additional work thrown upon them by the removal of the kidney of the other side, the same results obtain as in the rabbit series. There are no new anastomosing vessels between the capsule and the cortex. Up to two to three days there may be a rather marked cortical injection. A new capsule begins to be laid down by the tenth day. There is no change in the kidney epithelium or the glomeruli following the decapsulation. The kidney is increased in size immediately following the operation.

SUMMARY.

Following the decapsulation of kidneys in rabbits, in normal dogs, in dogs with induced nephritis, in dogs with infarcted kidneys, and in dogs with normal kidneys but with additional work thrown upon them I find the following conditions:

1. In all my cases of two days and under and in my controls the entire thickness of the capsule had been removed over two thirds of the surface by the operation of decapsulation.

2. There is a certain amount of intracapsular tension in undecapsulated kidneys, normal or with nephritis, as shown on removal of capsule.

3. There is an immediate increase in size of decapsulated kidneys persisting up to one month at least; afterwards, a decrease to approximately normal size complete at end of six months.

4. There is congestion, moderate in degree, most marked in the intertubular blood vessels in cortex, lasting three to five days after the operation.

5. No histological change in the renal epithelium follows the operation of decapsulation of kidneys.

6. A new capsule, very vascular, at first, two to four times thickness of old, is well marked at end of eight days. At end of six months it returns to approximately the normal thickness and vascularity. The new capsule arises chiefly from the connective tissue cells of the intertubular connective tissue, but in part from the retroperitoneal connective tissue which is present in the new bed of the kidney.

7. No new vessels are formed which anastomose with those of the kidney.

8. The increase in size is due primarily to the increase in blood supply, possibly resulting from the removal of the capsule.

FUNCTIONAL ALBUMINURIA, WITH A REPORT OF A CASE.[1]

BY J. BERGEN OGDEN, M.D., BOSTON.

DURING the past few months the subject of so-called functional albuminuria has once more been brought to the notice of the medical world, through the somewhat extended and very instructive discussion which took place before the Medical Society of London on Dec. 14, 1903. It is not my purpose, this evening, to consider this subject in its entirety, but rather to emphasize

[1] Read before the Harvard Medical Society of New York, May 28, 1904.

some of the points brought out by our English contemporaries, and to call to your attention a few of the most important features of functional albuminuria, — important because of their relation to the prognosis and treatment of this phenomenon.

A word in regard to the names given to this condition: It has been variously termed functional, cyclical, physiological, postural, dietetic, albuminuria of adolescence, and albuminuria in the apparently healthy. We have no knowledge of the pathology of the condition, so that we are obliged to content ourselves with a name which implies very little and which is vague. The term "functional," which was introduced by Dr. Pavy and which he still retains, is probably most commonly used, and I believe it is the most satisfactory name that we now have for the albuminuria of the healthy person. West [2] and Broadbent [3] are opposed to the use of the term "physiological," since they believe that an albuminuria can never be physiological. Broadbent favors the term "postural," because the condition is always dependent to some extent upon the position of the individual; in other words, when the person is in the upright position the urine contains a good amount of albumin, but when he is recumbent, the urine is free or nearly free from albumin.

Functional albuminuria is a condition in which albumin is generally absent from the urine on rising in the morning. After breakfast, or before, depending upon the activity of the individual, albumin appears, and the quantity usually increases as the day advances, up to a point where the amount remains fairly constant for the remainder of the day or to the time of retiring at night. In some cases, there is considerable fluctuation in the quantity of albumin at different times of the day, or active period, as will be seen in the case that I am to report.

The condition is most common among boys under the age of twenty. Because of its frequency during the greatest period of growth and development, the term "albuminuria of adolescence" has been quite appropriately applied. In these cases there is generally an absence of organic lesions, the persons apparently being in perfect health. The albumin in the urine is almost invariably found by either the insurance examiner or the family physician during his routine physical examination; occasionally by the person himself, in order to satisfy a curiosity.

There are apparently two important elements which enter into the production of an albuminuria at one time in the twenty-four hours and not at another: (1) Muscular activity, and (2) the ingestion of food. We know that the albumin makes its appearance as soon as muscular exercise begins; we also know that in most instances the amount of albumin in the urine increases after a meal, whether the food be rich in proteid or consist almost entirely of carbohydrates, in contradistinction to the views of Senator, Grainger Stewart, and others who have held that an albuminuria follows the ingestion of food rich in albumin. Dr. Pavy finds, however, that the diet does not play as important a part as exercise, and particularly excessive exercise. Over brain work is another important factor in the production of a functional albuminuria (Pavy).

We are at once confronted with the question of the manner in which exercise and the diet influence an albuminuria in these cases. It is probably connected in some way with the circulatory system, either through an increase in arterial tension, an undue permeability of the walls of the blood vessels in the glomeruli of the kidney, or a cardio-vascular instability as pointed out by Sir Broadbent.[4] Drs. Pavy and Armstrong [5] have each observed a violent cardiac impulse in these cases, and Dr. Broadbent states that in his experience it is the impulse of the right ventricle which is forcible, the apex beat being weak. The contrast between a weak apex beat and the left ventricle sounds, and the powerful right ventricle impulse and its loud sounds has been found by Broadbent to be constant in these cases. Another phenomenon pointed out by the same observer is that the second sound of the heart is reduplicated when the patient lies down.

The observations of these eminent authorities are sufficient to lead us to look to the circulatory system for the fundamental cause of functional albuminuria. We know that exercise, the ingestion of food, mental excitement, cold baths, and the like, result in an increase in cardiac activity and work, and probably, also, an increase in arterial tension. We are, however, still in ignorance of the condition of the blood vessels of the kidney, which will allow the passage of albumin into the urine of a person, whose kidneys are otherwise in apparently a healthy state.

N. F., a boy of nineteen years, was born in Brooklyn of Norwegian parentage, and has lived the greater part of his life in the outskirts of that city. For the past nine months he has been employed as a laboratory assistant.

Family history. — Mother and father living. His mother has had several attacks of what have been called kidney trouble. His father is said to have some affection of the heart. He has two brothers, both of whom are well.

Habits. — His habits are excellent. No history of any venereal trouble.

Past history. — Pneumonia when three, and measles when seven years of age. At the age of ten he was vaccinated; this was followed by suppuration of the arm and considerable toxemia, which kept him in bed for several weeks. Nine months ago, after a winter of hard study in high school, he had grip and was in bed for about one week. His health has otherwise been good.

Physical examination. — Well developed and fairly nourished. General appearance good. The heart was not enlarged and no murmurs could be made out. The precordial impulse was quite marked; the apex beat was very strong. Pulse 75, regular, and of good

[5] Ibid.

strength and volume. He was rather excitable. During periods of excitability his face was flushed and there were rather marked visible pulsations in the temporal and carotid arteries.

Present history. — Early in September, 1903, out of curiosity, he examined his urine for albumin and found that it was present to the extent of a very slight trace. My attention was called to his discovery, whereupon I examined the sediment with the following results: An occasional hyaline and granular cast with blood globules and renal cells adherent. An occasional free blood globule and renal cell. Numerous primary and secondary crystals of calcium oxalate.

An investigation was then started to learn the cause of the oxaluria, which seemed the most probable cause of the renal disturbance. Upon inquiry as to diet and habits of living, I found that he had been using for several years a " root beer " as a table drink, because of poor water facilities in the section of the city in which he lived. This beer was made from the preparation known as " Hire's Root Beer Extract," and was prepared by the addition of sugar, yeast and water, after which the mixture was allowed to ferment. The bottles were then kept in a cool place and one was opened as it was needed. The use of this drink was forthwith abandoned, and on Sept. 23, 1903, about ten days after the last " beer " had been taken, the whole amount of urine for twenty-four hours was examined with the following result: Twenty-four-hour quantity: 902 cc.; color, slightly high; reaction, strongly acid; specific gravity, 1,029; albumin, very slight trace; sugar and bile absent; uric acid and indoxyl, both relatively much increased; urea, 2.77%, making a total of 25.09 grams in twenty-four hours. Sediment: Occasional granular and brown granular cast with renal cells and blood adherent. Occasional free blood globule and free renal cell. A large excess of mucin and numerous secondary crystals of calcium oxalate.

The patient was then advised to drink a larger quantity of water during each twenty-four hours and was given a tonic consisting of iron, quinine and strychnine, which resulted in an improvement of the appetite, and general condition.

Another twenty-four-hour quantity was collected on Oct. 15, 1903, the analysis of which gave the following: Total quantity in twenty-four hours, 1,220 cc.; color, normal; reaction, strongly acid; specific gravity, 1,025; the uric acid and indoxyl still relatively increased; albumin, slightest possible trace; bile and sugar, absent; urea, 2.08 present or 25.38 grams in twenty-four hours. Sediment: Occasional hyaline and granular cast with renal cells adherent. Rarely a blood globule and an occasional renal cell. An excess of mucin, and an occasional primary and secondary crystal of calcium oxalate.

All treatment was then stopped with the exception of the ingestion of plenty of water. Further systematic examinations of the urine were not thought necessary, but about once a month tests for albumin were made, and amounts varying from the *slightest possible trace* to a *slight trace* were invariably found. In December, 1903, although the albumin persisted, the sediment was found to be free from casts and other formed renal elements, and calcium oxalate crystals were absent. In January, 1904, a very thorough examination of the sediment failed to reveal the presence of any renal elements or an oxaluria, although the specimen contained a very slight trace of albumin. Still another specimen examined in February, 1904, gave the same result as those during the two previous months.

I had already become convinced of the fact that the albuminuria was dependent on something besides a disturbance or disease of the kidneys, since renal casts, renal cells, and blood could not be found during prolonged microscopic examinations of both centrifugalized and gravity sediments. Furthermore, that the general condition of the patient and the absence of physical or clinical signs did not point to any pathological changes in the kidneys. There was also no evidence of any local disease of the urinary tract to account for the albuminuria.

A complete quantitative analysis of the urine on March 2, 1904, gave the following: Quantity in twenty-four hours, 1,660 cc.; color, slightly pale; reaction, acid; specific gravity, 1,016; albumin, very slight trace; bile pigments and sugar, absent. Sediment: Rarely a blood globule. A few spermatozoa and a slight excess of neck of bladder cells. No casts could be found. Urea, 33.53 grams; uric acid, 0.68 gram; phosphoric acid, 1.31 grams; sodium chloride, 14.44 grams; preformed sulphates, 3.07 grams; ethereal sulphates, 0.083 gram; albumin, too slight to accurately quantitate.

This examination furnished no adequate cause of the albuminuria, the exceedingly slight neck of bladder irritation being insignificant. The output of uric acid was found to be somewhat excessive, while the excretion of total phosphoric acid was about one half the average normal. All of the other solid constituents were being eliminated in normal quantities.

A noticeable feature of the case was the varying amounts of albumin at different times of day, and it seemed to me important to determine the degree of variation by the examination of hourly specimens. It seemed also advisable to determine the effect of exercise and diet on the output of the albumin.

[6] Figures given only when sufficient albumin to quantitate.

In March Mr. F. decided that he would try a change of occupation which would give him a greater amount of out-of-door exercise. Accordingly, about the 20th of the month, he took up carpenter work. Within one month he had gained about 10 pounds in weight, and was feeling very much better in every way than when he was confined to the work of the laboratory. I was naturally curious to know the effect of the unusual amount of exercise upon his urine. An analysis on April 23 gave the following results: Total amount of urine, 1,200 cc.; color, high; specific gravity, 1,029; reaction, strongly acid; urea, 2.4% or a total of 28.8 grams in twenty-four hours; uric acid, 0.58 gram in twenty-four hours; albumin, a very slight trace. Sediment: Rarely a blood globule. No casts or other formed elements which were significant.

On April 27 he made an effort to save hourly specimens, but he found it impossible. He, however, saved a number of samples, a record of which is given in Chart VII.

— from 12.15 to 4.10. This resulted in a complete disappearance of the albumin from the urine of that period.

The amount of albumin was, of course, somewhat dependent on the concentration of the specimen, but the charts show that in the majority of instances the specific gravity was in the neighborhood of 1,021, the extremes being 1,012 and 1,029. The percentage of urea varied between 1.01 and 3.68, the average for each day being generally above 2%. The qualitative tests for uric acid usually showed a relative excess, but in the quantitative determination, the quantity did not exceed 0.68 gram in twenty-four hours, — a moderate absolute excess.

The diet was, if anything, a little low for a growing boy, and there was lack of variety in the food, but what was taken was substantial,

CHART VII.

[6] Figures given only when sufficient albumin to quantitate.

Although we are unable to compare this chart with the preceding ones, because of the length of time between the individual specimens, it is plainly evident that the albuminuria was no more marked than six weeks before; indeed, the chart would, if anything, indicate less albumin than when the earlier observations were made.

We have in this case what I consider a fairly typical instance of functional albuminuria. The boy was apparently in every way healthy. Aside from a neurotic temperament, the albumin in his urine was the only thing to attract attention. The urine was generally free from albumin on rising in the morning. The amount then rose to a maximum of 0.05% in one instance (Chart VI). A study of the charts shows that the quantity of albumin was usually small, the fluctuation in quantity being largely due to the amount of exercise taken, and also, to a less extent, to the intake of food, irrespective of its quality or quantity. There was a lack of uniformity in the fluctuation. Generally, the largest amount of albumin was found in the evening or after he had reached home and had had his dinner; this was, however, not invariable, for in a few instances the quantity was no larger than at other times in the day. The experiments tried and recorded in charts V and VI are instructive. On one occasion (Chart V) no luncheon was taken but he remained active; the amount of albumin was apparently not affected. On another day (Chart VI) he was requested to lie down for four hours, and was apparently all that he required to maintain his weight and strength.

For the nine months previous to March 20, the exercise which he took was never excessive or violent. It consisted of walking at an average pace. In the laboratory he was on his feet the greater part of the time, standing or walking about the room. He was not obliged to do heavy work of any kind. After March 20 he had violent exercise and hard work, and yet the albuminuria was no more marked because of the change of occupation.

The proteid in the urine of this case consisted almost entirely of serum albumin. Repeated tests were made for globulin and for albumoses, but always with negative results. There was, however, a minute trace of nucleo-albumin in each of the samples tested; the amount was so small that I believe that we can disregard it.

A good deal of interest is attached to the relation between the renal disturbance and the oxaluria discovered in September, 1903, and the use of the "root beer." I was convinced that the very mild disturbance of the kidneys was in all probability due to the mechanical action of the crystals of calcium oxalate, for as soon as the oxaluria had disappeared the irritation of the kidneys was gone. I was inclined to suspect the "root beer" as the cause of the oxaluria, because of the number of roots and herbs which the preparation is supposed to contain. "Hire's Root Beer Extract" is supposed to be made

from hops, juniper berries, pipsissewa, sarsaparilla, spikenard, etc. The fermented preparation, when ready for use, was found to have a strongly acid reaction, and an acrid and sweetish taste. Microscopic examination of the deposit in the bottle showed the following: Starch and vegetable cells, spores, a little oil and much amorphous matter; numerous needles, plates and prisms; numerous octahedral crystals resembling those of calcium oxalate. I made an effort to quantitate the oxalic acid in the beverage, but for some reason I was not successful, and this led me to suspect that the octahedral crystals were perhaps not calcium oxalate, but rather a crystalline glucoside from the sarsaparilla or some of the other vegetable constituents of the beer. I have not yet been able to satisfy myself of the nature of these crystals.

The fact remains that there was some relation between the ingestion of the root beer and the oxaluria, either through an excess of oxalic acid in the beverage, or through an abnormal degree of intestinal fermentation set up by the beer. In this connection Simon [5] mentions having seen an albuminuria follow free indulgence in root beer, but he makes no reference to a coexisting oxaluria. I have not succeeded in finding any mention of similar instances of the effect of the free use of this beverage.

The root beer had been used a number of years by Mr. F., and we naturally are confronted with the question of the amount and extent of the damage to the kidneys by the long continued use of the preparation. From the fact that the slight irritation of the kidneys cleared up in about four months, as was manifest by the disappearance of casts and the other formed renal elements, I feel quite certain that any damage that might have been produced by the use of this beverage had been fully repaired, for if such were not the case, with the amount of albumin found, we would be very certain to find casts at some time, and yet no casts could be detected during a number of thorough microscopic examinations which have been made since October, 1903. I therefore believe that we can eliminate the possibility of an incipient chronic disease of the kidneys in this case.

The prognosis in these cases is favorable in the great majority of instances. Broadbent states that he has never known postural albuminuria to resist treatment or to develop into actual renal disease. Pavy has watched cases for upward of fifteen years, and he is satisfied that functional albuminuria must be regarded as something besides an incipient stage of organic renal disease.

The treatment is simple, and the reverse of what is ordinarily considered suitable in renal disease. The treatment that is usually required is good, simple food, fresh air, and vigorous exercise. Tonics, such as iron, arsenic, quinine and strychnine, are useful in many of these cases. Dr. Broadbent has emphasized one important point, *i. e.*, that if there has been an error in diagnosis and the patient is treated for renal disease by giving a milk diet, protecting from cold and forbidding exercise, he will probably go from bad to worse; he has met with several instances of confirmed nervous valitudinarianism, apparently attributable to this error in diagnosis during the early life of the individual.

[5] Clinical Diagnosis, 4th edition, p. 407.

COAGULATION-TIME OF THE BLOOD.

A COMPARISON BETWEEN THE WRIGHT AND THE BRODIE-RUSSELL INSTRUMENTS, BASED UPON SIX HUNDRED OBSERVATIONS.

BY F. T. MURPHY, M.D., AND A. H. GOULD, M.D., BOSTON.

For the Division of Surgery of the Medical School of Harvard University.

THE coagulation-time of the blood is the interval which elapses between the moment of the withdrawal of the blood from the body and the moment when the blood coagulates. To determine this interval for clinical purposes, five methods are used: (1) The simplest procedure is still extensively employed, and requires merely that a drop of blood be placed upon a clean glass slide. The consistency of the blood is periodically tested by moving the drop with a needle. When the blood becomes gelatinous and fibrin shreds are thus demonstrable, coagulation has taken place. This is plainly crude technic. It cannot be relied upon to indicate a delayed coagulation, because of the rapid evaporation which occurs, upon subjecting the drop to the direct action of the air. (2) A decided improvement upon the old method just described is the microscopic examination of the blood. A fresh drop is placed upon a slide and covered with a cover glass. The blood is watched with the microscope until delicate fibrinous processes make their appearance. The recognition of the first shreds of fibrin is said to mark the end of the coagulation-time; but, since these shreds do not appear simultaneously in all parts of the drop, the method is inaccurate. (3) In the third method, described by Vierordt in 1878, a drop of blood is drawn into a capillary glass tube. A piece of horse hair, which has been properly cleaned, is inserted into the column of blood in the tube, and is moved up and down, at intervals. When the blood adheres to the hair, the moment of coagulation has come. The writers have had no success with this method and do not recommend its use.

In 1893 A. E. Wright constructed an apparatus, consisting of a number of similar, carefully calibrated, capillary tubes. A drop of blood drawn up into one of these tubes will adhere to the lumen when coagulation takes place. The exact moment when this adhesion occurs is determined by moving the blood column from time to time. This is done by blowing gently into the tube. When no response to this air pressure can be obtained the column of blood is coagulated. Several observations are made in this manner upon blood taken at regular intervals. No reliable results were obtained, by attempting to

judge of the degree of coagulation from the consistency of the column of blood when forcibly expressed from the end of the tube. It was at first thought necessary to protect the blood from changes in temperature by suspending the tubes against a water bath. This measure has been found to be superfluous, and now no particular effort is made to keep the blood at body temperature. The favorable results reported by Wright and others, in cases where this instrument was employed, led to its use by the writers. In this series of cases, an attempt has been made to find the simplest and most accurate instrument. For this purpose the Wright apparatus was compared with the (5) Brodie-Russell.

The last method to be described is a device of T. G. Brodie and A. E. Russell. Although introduced in 1897, it has not been so widely used as it merits. The original apparatus was furnished with a water bath to keep the moist chamber at body temperature, and with a stage to regulate the size of the drop, two features which made the apparatus complex and costly. The modification devised by Prof. Guntzner and Dr. J. H. Pratt simplified the construction by omitting the water bath and stage without impairing the accuracy of the instrument. This modified apparatus was used by us.

The instrument is made by fastening a metal ring about 5 mm. in height and about 2 cm. in diameter to the surface of a glass slide. A hole in one side of the ring admits a small metal tube to which is attached a rubber tube and bulb, while, on the opposite side of the ring, is a second hole which provides for the escape of the air current. The end of the metal tube is bent slightly upward so that, by moving the cover glass, the air may be directed on the edge of the drop of blood. The upper edge of the ring is anointed with vaseline, and a drop of water placed in the chamber formed by the ring and the glass. A drop of blood is caught on a heavy cover glass and the latter placed upon the ring so that the blood drop projects into the moist chamber. The vaseline prevents the entrance of air around the edge of the ring and holds the cover glass in place. The drop is now watched with a low power microscope, while a current of air is forced through the metal tube. In this manner the corpuscles are set in motion. At first the motion may be irregular, but soon a ring of serum separates at the edge and the whole drop rotates. As the end of the coagulation-time approaches translucent masses appear throughout the drop of blood. These masses increase rapidly in size, and about them coagulation seems to take place. The moment when the edge of the drop of blood fails to rotate in response to the air current marks the end of the coagulation-time. This phenomenon may take place slowly or suddenly. As a control in all cases the cover glass was removed and the blood drop pricked with the point of a needle. Demonstration of fibrin shreds was regarded as final evidence that coagulation had occurred.

The technical difficulties of the Brodie-Russell are fewer than those to be encountered when using the Wright instrument. If the drop whirls at all in the moist chamber, a practically accurate coagulation-time can be obtained. Occasionally the drop cannot be made to rotate by the air current. This is usually due to uncleanly technic, but is sometimes caused by the exposure of the drop to a cold draught.

The Wright tubes are cumbersome, easily broken, and difficult to clean. It is not possible to tell at once whether or not the preparation will be a successful one, as can be done with the Brodie-Russell. In a certain number of cases the blood will not coagulate at all. The failure of the blood column to adhere to the lumen of the Wright tube cannot always be explained. Although sometimes if the blood is moved, just as coagulation takes place, the serum collects around the outside of the clot, and an adhesion between the clot and the tube will never take place. This failure to adhere is the greatest imperfection in the method, because there is no way of determining the coagulation-time without moving the blood. From this and other causes the Wright instrument failed to give results in 15% of the observations, while the Brodie-Russell failed in less than 5%.

It is probable, as stated by physiologists, that the contact of the blood with the tissues outside the vessels causes, in some way, the elaboration of a fibrin ferment. If the needle prick is a deep one, the rapid flow of the blood will wash away the ferment and prevent immediate coagulation. The reverse is true of a superficial prick. It is obvious from this that the needle prick should be deep enough to cause a free flow of blood, and that only the first few drops of blood should be used.

In this series of 59 cases, we have used the Wright tubes and the Brodie-Russell moist chamber side by side. The experiments were done in open wards and in small rooms, at the Massachusetts General Hospital, where the temperature varied between 51.8 and 85 degrees Fahrenheit. The coagulation-time was not found to be influenced by the temperature within these limits. Six observations were made with each instrument on 42 of the cases. In the remaining cases, the scheme of 12 observations on each patient could not be carried out.

The surface of the skin was cleansed with soap, water and alcohol, and the glass instruments with water, ether and alcohol. The blood was drawn from the surface of the body in three places, namely: from the lobe of each ear and from the ball of a thumb, a large triangular needle being used for the puncture, to insure the free flow of blood.

There have been no marked differences between the coagulation-times of the blood-drops taken from different points on the surface of the body, provided the flow has been equally free, although the contrary was observed by Pratt. The writers are convinced, from numerous tests, that if several drops of blood are taken simultaneously from different points on the surface

of their body, their coagulation-times will coincide, if the technic is perfect. Our results have not always shown the coagulation-times to be exactly the same when done with two instruments at the same time. The variations beyond a reasonable limit of error have been few, and might be explained by faults in technic. The average coagulation-time with the Brodie-Russell instrument in 300 observations was three minutes and twelve seconds; the average with the Wright was four minutes and eighteen seconds. This result is somewhat lower than that usually given.

Variations were found in health between one and seven minutes with both instruments. We attribute the extremes to technical errors. The limits are presumably three to six minutes. The proof of a delayed coagulation must be based on several observations, in order to minimize the influence of technical errors.

In this series are included 15 jaundice cases, the lesions of which embraced nearly every known cause of jaundice, *i. e.*, gallstones, catarrhal jaundice, cholecystitis, cirrhosis of the liver, cancer of the liver, cancer of the head of the pancreas, chronic pancreatitis, etc. It is of interest to note that in none of these cases did the coagulation-time vary from the normal.

The conclusions to be drawn from these observations are as follows:

The Brodie-Russell is more reliable than the Wright instrument.

The average coagulation-time is between three and six minutes.

The proof of a delayed coagulation must be based upon several observations.

The coagulation-time is not affected by the ordinary changes in room temperature.

Blood obtained simultaneously from different points on the surface of the body shows no marked variation in the coagulation-time.

A delayed coagulation is not constantly associated with jaundice due either to benign or to malignant obstruction. [The writers are greatly indebted to the visiting Staff of the Massachusetts General Hospital for their courtesy in providing material for these observations.]

Clinical Department.

ADENO-CARCINOMA OF INTESTINES INVOLVING THE BLADDER.

BY SARAH ELLEN PALMER, M.D., BOSTON,

Surgeon to New England Hospital and to the Charity Club Hospital.

E. C. Single. Fifty-seven. Overworked and nervous. Poorly nourished, appetite good, bowels regular. Has been losing flesh pretty steadily. Patient was well, so she says, until one year ago, when she had two attacks of grip, since which time she complains of frequent micturition accompanied by burning and smarting, until six months ago when she had an acute illness of which the nature was not very well determined. Chills, rise of temperature, and abdominal tenderness. During the time of confinement to bed the bladder annoyances were diminished and urination less frequent. Five months ago the present condition of frequent urination during the day and the need to rise four or five times during the night has existed. Occasionally blood is seen in the urine and shreds of some foreign substance. At times a clot of blood is expelled with pain, and of late the urine is often tinged with blood. Menstrual history uneventful and menopause at fifty. Three years after this, on occasion of a slight bloody discharge from the vagina, she was sent by her physician, Dr. Reid, to Dr. Call, who relieved this symptom and who found at that time no other lesion. Urine examined with negative results. On the 13th of November, 1903, Dr. Call referred her to me, with the history as given above.

Patient thin and pale. Abdomen flat and somewhat resonant to percussion. Vulva in process of senile atrophy and vagina partly involuted. Uterus was found to be, apparently, of normal size and sharply anteflexed, a little drawn to the right. Bladder examined cystoscopically under cocaine. Urethra somewhat congested in contrast to the bladder wall which, thoroughly well ballooned, was healthy in appearance, except a grayish mass a little to the right of and anterior to the fundus, apparently about three cm. by two cm. in width, and from the mass finger-like, club-shaped filaments extended into the bladder, giving the appearance of a coronoid polyp described by Clado. A small piece scraped off and sent to Dr. W. F. Whitney for examination.

Microscopic examination showed the piece sent to be composed of vascularized soft, cellular, connective tissue, surface of which was papillary and covered with a single layer of long columnar epithelium.

Diagnosis: *Papilloma.* — Several subsequent examinations were made in the office, and on two occasions the bladder seemed perfectly healthy; the gray mass could not be brought into view through the contracted bladder wall. Examined under ether at the Charity Club Hospital Dec. 3. Cystoscopic appearance as described above. Uterus apparently in normal position, and what had been supposed to be the body gave the sensation of a fibroid. The small finger introduced into the bladder after dilating the urethra. Bladder wall perfectly smooth for two thirds of the distance, then the finger entered a crypt through the contracting bladder wall, giving the sensation of the ring of Blandl in hour-glass contraction of the uterus with the placenta above. And so, in this case, the finger could sweep about a perfectly smooth bladder and then enter a crypt or cul-de-sac and come in contact with a soft spongy mass. Large mass scraped off and sent to Dr. Whitney, and the following statement returned: "The specimen from the bladder of Miss E. C. consisted of some tissue in which there was considerable thick mucus. Microscopic examination showed a fibrous tissue structure in places and distinctly myxomatous degeneration. As far as this specimen goes, the diagnosis is a myxoma."

Examination of the urine by Prof. E. S. Wood, who reported: "I am unable to find in the sediment of any of these specimens any evidence of malignant growth of the bladder. I am unable to find any cells which are at all suggestive of morbid growth. I do find, however, in the sediment of all these urines, even in the specimen passed after the bladder was washed out, particles of food, such as vegetable cells and partly digested muscular fiber. It does not seem to me rea-

sonable that these could have got into the urine after it was passed, and if they were in the urine while in the bladder, they show that there must be some connection between the intestine and the bladder. The urine also has a slight fecal odor. There is a good deal of suppuration which would be expected, of course, if there were a sinus between the intestine and the bladder. All that I can say about these specimens is, that they point more strongly to this diagnosis than to the existence of a morbid growth in the bladder."

After Dr. Wood's report we decided to open intraperitoneally, although my first idea had been to do a suprapubic cystotomy external to the peritoneum. While the patient was being prepared for operation, stimulated by Dr. Wood's report, I thought I could detect distinct gurgling in the mass anterior to the uterus.

Abdomen opened after the usual antiseptic precautions. On lifting the omentum the small intestine presented the usual grayish appearance with the exception of an intensely congested loop high in the abdomen. Uterus atrophied in good position and the ovaries sclerotic. Attached to and communicating with the bladder was a loop of small intestine. The lumen of the intestine was encroached upon by a new growth, soft to touch and deep crimson in color, forming half the wall of intestine and extending into the bladder. When the intestine was detached from the bladder, the cavity of the bladder opened directly into the abdominal cavity. The cecum formed a hard contracted mass attached to the right of the bladder, easily detached from the peritoneum covering the bladder and separated from the soft infiltrating mass, described above, by clean bladder wall. Appendix identified, small and anemic, and in usual relation to the bowel. Between the diseased cecum and the soft mass in the small intestine were loops of apparently healthy bowel. The cecum was with some difficulty detached from the broad ligament which was involved out to the pelvic wall in a small, hard, cartilaginous tissue. Special mention is made of this because in the final pathological report it is seen that the pathologist believes that the carcinoma originated in the cecum. The small intestine was detached from the bladder and resected. About 5 cm. of intestine were cut out and with it all the wall involved in the growth; two healthy ends brought together and united by the double Lembert suture of silk by the aid of Harrington's ring. The fundus of the bladder was also resected, removing the diseased mucous membrane from the bladder as far as possible, and the top of the bladder closed with a double row of Lembert suture, using chromicized catgut. Permanent catheter left in the urethra. The cecum was detached from the bladder and separated from the bowel by shoemaker stitch of catgut and then cut off. It was impossible to completely remove the diseased area, so extensive was it found to be in the peritoneal cavity.

The patient, although fifty-seven, was really a feeble old woman and in poor condition to stand so extensive an operation. Salt solution was given in large quantities into the breasts; gauze drainage was left in abdominal wound, and the rest of the wound sutured with through-and-through silkworm gut.

The patient rallied well from the operation. For twenty-four hours the amount of urine was small. On two occasions a leak of urine through the abdominal wound occasioned fear of permanent fistula, which, however, proved to be groundless, and the patient left the hospital the 4th of March, able to hold urine in the bladder for a period of three or four hours and to void it without difficulty. Bowels moved without trouble on the third day, and since that time with very little difficulty. Convalescence was slow in this underfed and delicate woman. The abdominal wound, after the stitches were removed, had made no effort to unite above the fascia. It simply fell apart in two dry surfaces, but, as she improved, this granulated up and was completely healed when patient left the hospital. The patient at present writing is at her own home and in fairly good condition.

PATHOLOGICAL REPORT FROM DR. WHITNEY.

The specimen received from you, Dec. 19, 1903 (T. 311–10 C), consisted of two pieces of intestine and some irregular fragments from the bladder wall. Examination showed the piece from the head of the colon to be a tubular mass about the size and half the length of the thumb. One end showed the normal structure of the intestine while the other was irregular and ragged as if from a new growth. Upon opening this mass there was a small tubular thickening on one side about the size of a Fallopian tube, and about 3 cm. in length. This opened freely into the cavity of the intestine. The other end was lost in a ragged new growth.

Microscopic examination showed the structure of the new growth to be that of an adeno-carcinoma with extensive mucous degeneration. The piece of small intestine showed a portion of a similar growth adherent to the outside, and into this was a fistulous opening from the interior of the intestine.

Microscopic examination of the piece of tissue from the bladder wall showed an infiltration of a similar new growth.

Diagnosis: Adeno-carcinoma of the head of the cecum involving the bladder and intestine.

In conclusion, I have to thank Dr. Charles H. Hare, who kindly assisted at the operation as well as at the etherized examinations, also Drs. Wood and Whitney, who gave their valued assistance and encouragement, and the house officers of the Charity Club Hospital.

Reports of Societies.

AMERICAN GYNECOLOGICAL SOCIETY.

TWENTY-NINTH ANNUAL MEETING, HELD IN BOSTON, MASS., MAY 24, 25 AND 26, 1904.

(Continued from No. 1, p. 20.)

FIRST DAY. — (Continued.)

SURGERY OF THE FEMALE URETHRA.

DR. ELY VAN DE WARKER of Syracuse, N. Y., read a paper on this subject. The urethra, he said, appeared like an insignificant part; its vital relations were negligible, its anatomy was relative and acquired its importance from its related organs, but it might be said to epitomize a large share of the suffering that woman's pelvic organs inflicted upon her. The amount of disturbance caused by a simple irritation of the urethra to the bladder, and indirectly to the kidneys, afforded striking proof of the validity of reflected nervous disturbance.

The term sacculation was regarded as better than the old one, urethrocele. Its major cause was mechanical, as inflammation alone was not adequate to its production. The urethra might be said to belong to the perineal rather than the pelvic zone of organs. The walls of the canal depended in a measure upon the support of the perineal body. It was often associated with long-standing rupture of this part. Restoration of the perineum was, therefore, essential to treatment of the sacculation. When large, an elliptical flap of the walls of the urethra was removed and the edges brought together by fine silk sutures. Prolapse of the mucous lining of the urethra the author had generally associated with long-standing urinary troubles of various kinds. It was, therefore, probably

due to a gradually progressive condition, and was a typical ptosis, and complied with the general law of genital prolapse. After removing the prolapsed portion, there was a marked tendency to recurrence unless the conditions which gave rise to it were treated and cured. Bladder incontinence and dribbling were often lifelong conditions. That this was due to a defective action of the sphincter vesicæ was more than doubtful. Dribbling was one of the symptoms of hysteria, of which a striking case was given in illustration.

Narrowing, by operation, the bladder and end of the urethra, linear cauterization at this point had afforded relief. Any treatment was liable to fail, and relapses were frequent. The powerful influence of hysterical disturbance over the urinary tract was constantly observed. Dribbling was the related phase of retention. The treatment of this form was more satisfactory. The urethral stricture, when of small caliber, was frequently found with dysuria and dribbling. The author referred to but two cases of urethral mucous polypus, and concluded that they must be rare. These growths ought never to be twisted off, as the tissues were too friable. Removal of the growth through the mucous membrane, so that no stump was left, was the proper procedure.

Stricture of the urethra, in the author's experience, is common in women. Any condition that tended to produce linear or annular thickening thus led to stricture. Specific urethritis might produce stricture, but it was not the frequent cause alleged by some writers. Stricture of large caliber might be located and measured by the Otis bulbs, but never by the sound, as was recommended by old systematic writers. Annular stricture of the meatus was the form most commonly met with. This ought to be incised and made to heal in an open condition by the frequent passage of the sound. Dilatation alone was too painful and required too much time. As to eversion of the mucous membrane at the meatus its prototype was the fusiform stricture of Otis, and its surest cure was by dilatation. Caruncle of the urethra was a common occurrence. Removal, involving the whole thickness of the mucous membrane, being careful not to leave a stump, was an effectual cure.

PYELITIS COMPLICATING PREGNANCY.

Dr. Edwin B. Cragin of New York said the occurrence during pregnancy of a marked rise of temperature, with pain and tenderness on the right side of the abdomen, was always a source of anxiety to the obstetrician. Although several able articles describing the condition had appeared, it was not generally recognized that pyelitis was not an infrequent cause of the above symptoms. It might be confused with appendicitis, typhoid fever, or salpingitis. It occurred almost, if not quite, invariably on the right side. It was due to pressure on the ureter by the pregnant uterus plus an infection. This infection was usually descending, and was usually due to the colon bacillus. The urine was acid, contained at first albumin and perhaps a few casts, soon followed by pus and bacteria. The prognosis was usually good. Induction of labor was seldom indicated. The medical treatment by urotropin, or allied drugs, with ice bag over the kidney, fluid diet, and large draughts of water was usually sufficient.

A SECOND CASE OF PUERPERAL ECLAMPSIA SUCCESSFULLY TREATED BY RENAL DECAPSULATION.

Dr. George M. Edebohls of New York said the first case, reported to the society a year ago, illustrated the immediate cure by renal decapsulation of puerperal convulsions, recurring with great and increasing violence after the birth of the child, a period at which the hitherto final resource of forced delivery was, of course, no longer available. In presenting the case the opinion was advanced that resort to renal decapsulation in the undelivered woman suffering from puerperal eclampsia might obviate the necessity of forced delivery. The case now reported illustrated the correctness of that opinion. Renal decapsulation was performed upon a woman pregnant near term, suffering from puerperal eclampsia, and almost complete suppression of urine. The convulsions were arrested, the flow of urine was re-established, and a threatened death from uremia was averted. Two days after all this had been accomplished labor began spontaneously, and living twins were born. One child died soon after birth. The second child and the mother were in perfect health four and one-half months after the termination of pregnancy. Renal decapsulation thus became the rival of forced delivery in cases of puerperal convulsions of renal origin in the undelivered woman. In puerperal convulsions, occurring or recurring after delivery, it constituted the final resort when all other measures had failed.[1]

Second Day.

PRIMARY REPAIR OF LACERATIONS OF THE CERVIX UTERI.

There was a symposium on this subject. Dr. Edward P. Davis of Philadelphia read the first paper. Experience in fifty-three cases had led to the following conclusions: When the patient was not infected, and when the tissues had not been subjected to sufficient violence to threaten necrosis, and laceration of the cervix, one-half inch or more in extent, was present, primary closure had been followed in his experience with good results. These cases usually occurred in primiparæ, where resistance in the soft parts occasioned sufficient delay and fatigue to require delivery by forceps. They were also seen in cases of premature labor, whether spontaneous or induced, where the cervix was not physiologically softened for perfect dilatation. They were also found in patients having spontaneous labor with very strong expulsive efforts, and with large children. Naturally those cases in which the mechanism of labor was abnormal through posterior rotation of the occiput, face presentation or breech presentation, predisposed to laceration of the cervix. While primary closure of laceration of the cervix was indicated in the conditions just described, certain conditions were necessary for its successful performance. These conditions were outlined. Dr. Davis then described the technique of the operation and the after-treatment.

The number of cases under observation was 53. In these, good union occurred in 45, fair union in 6, no union in 7, while infection developed in none. In 84.9% the operation was successful; in 11.3% it was moderately successful, and in 3.8% the operation failed. The percentage of infection was *nil*.

He pointed out the objections which were commonly urged against this operation, after which he said that in appropriate cases in his experience, immediate closure of the cervix had given no inconvenience to the mother, and had been followed by excellent results. The operation was not advised for those who do not practice obstetrics with good surgical technic, and who were not competent to operate on the genital tract.

[1] For the full paper see Journal, Vol. CL., p. 586, 1904.

THE PRACTICE OF CERVIX SUTURE ON THE FIFTH DAY AFTER DELIVERY.

DR. ROBERT L. DICKINSON of Brooklyn said that no complicated or considerable perineal injury should be repaired at the close of labor, but three to five days later. This had an important bearing on lacerations of the cervix, as this was the ideal time to restore such injuries. The huge edema, the bruising, and the uncouth distortion of the vaginal portion just after delivery rendered identification of the parts that should be brought together impossible, and attempt to accurately coapt, guesswork. Therefore, whenever possible, the cervix should be sewed on the fifth day. The frozen sections of the puerperal weeks showed that then, and not till then, shrinkage had occurred. Bleeding no longer obscured the difference between flayed surface and torn structure. Then only were the surroundings of the operation, in the way of illumination, table, time, and a rested personnel possible. This applied particularly to private practice.

The conditions under which the cervix should be repaired at the close of labor were : (1) Bleeding from a firmly contracted uterus, notwithstanding ergot, heat, holding, and tampon. Here there was a spurting artery. (2) When the cervix injuries were clean cuts, of known location, as after Dührssen incisions. (3) When, in the immediate repair of a moderate perineal injury, a tear of the cervix is found.

The conditions under which the cervix should be repaired several days after labor were: (1) Exhaustion of patient, or surroundings and conditions which precluded careful work. (2) Extensive injuries, except when these persistently bled or had been cut by the surgeon. (3) When accompanied by complicated or considerable injuries to the pelvic floor.

The author drew attention further to the alterations produced by granulation and contraction in these wounds when left alone, so that the scarred, swollen, everted, or cystic cervix months or years after injury gave uncertain indications for accurate restoration to the original condition.

GENERAL CONSIDERATIONS OF LACERATION OF THE CERVIX UTERI.

DR. J. M. BALDY of Philadelphia stated that as a matter of clinical fact, let the cervix uteri be torn deeply, and if the parts were preserved from infection, the greater part of the tear would heal spontaneously, and the rest of it would remain perfectly healthy, as much so as would the lobe of the ear which had been torn through by the weight and drag of our great-grandmother's earrings. The lips would remain uninfiltrated, of normal size and thickness, with no eversions and no erosion of the lining mucous membrane. In such a case there would be no untoward symptoms and no bad effects whatever.

There was a tendency amongst obstetricians to repair these lacerations primarily. The objections to such practice were manifold, and he admitted a prejudice against it. These objections were pointed out. Whatever might be ideal surgery under the exigencies of actual practice, the treatment for recent lacerations of the cervix remained, and he believed would remain, rigid local cleanliness, excepting where there was sufficient hemorrhage to demand a ligature. Where non-infection could be insured, and where the torn lips were not unnecessarily disturbed by the careless use of the nozzle of a syringe, spontaneous healing of these lacerations might be expected to a greater or less degree, and what tear remained, when nature was through with her work, would be of a healthy character, would give no future trouble, and would need no surgical interference.

The symptoms of chronic lacerations of the cervix uteri were essentially local in their production and remained so in their manifestations. He had no sympathy with the views which attributed reflex symptoms to these lesions. In uncomplicated cases, where there simply existed a laceration of the cervix uteri, with everted and eroded lips, producing a constant leucorrhea and a feeling of weight and uneasiness in the pelvis and about the rectum, these so-called reflex symptoms did not exist.

There was one belief prevalent which would warrant, nay, demand, a repair of every lacerated cervix — the belief that lacerations of the cervix produced carcinoma. In this belief he took no part, and no one had to his knowledge as yet produced a single scientific fact which would uphold such a theory.

In twenty years' work he had not seen a single case of cancer develop in a laceration of the cervix which he had refused to repair.

INTRAPELVIC HEMATOMA.

DR. J. WHITRIDGE WILLIAMS of Baltimore reported a case of intrapelvic hematoma following labor, and made some remarks on the treatment of incomplete rupture of the uterus.

PRESIDENT'S ADDRESS.

DR. EDWARD REYNOLDS of Boston in his presidential address said, among other things, that the society owed its pre-eminence along its chosen line less to the words than to the prolonged and daily labor of the eminent men who had composed it in the past, and must owe its future to the lifework of the equally able men who were to fill its membership in the coming years.[2]

(To be continued.)

Recent Literature.

Studies in Heteromorphosis. By H. CHARLTON BASTIAN, with 815 illustrations. 8vo. pp. Williams & Norgate. 1903.

It is a sad task to call attention to this work, which, now that it is completed, has gained nothing in value beyond what belonged to the first part, of which we printed a notice in this JOURNAL upon its first publication. The author is unfortunate in making the ambitious attempt to overthrow the fundamental conceptions of biology, as to species, heredity, the genetic relations of forms, etc., by maintaining that by "heteromorphosis" one form of low life may give rise to another entirely different, as bacilli and eggs of rotifers to protozoans! He lacks the very most rudimentary conception of scientific proof, and the elementary ideas as to experimentation which we might expect of a schoolboy. It is only necessary to say that his typical experiment is to put stagnant water with vegetable matter in an open flower pot. Finding, at first, one species plentiful and days or weeks later another species plentiful, he has "proved" that the first has changed into the second. It is hardly necessary to add that the book is in no sense a scientific publication, and should be forgotten as speedily as possible.

C. S. M.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JULY 14, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 Bromfield Street, Boston, Mass.

BOSTON'S CHRONIC SICK.

There is every evidence to show that the best sentiment of the public is coming to regard the person ill with chronic disease in the same general category as the person ill with an acute disease. That such a recognition should have been so slow in coming is certainly a matter of regret, but that the chronic sick in this city, as in others, are likely hereafter to have adequate hospital care with the appurtenances which go with a modern hospital is hardly to be questioned. In view of the vicissitudes which the Long Island Almshouse and Hospital of Boston has experienced during the last few years, in the attempt to establish a hospital in the best sense of the word, it is gratifying to record the fact that at the recent exercises of the graduation of nurses, the Hon. John B. Martin, in charge of the institution, affirmed that the hospital idea as there developed had come to stay. Mr. Martin no doubt expressed the wide public sentiment which is shared not only by physicians who are at all acquainted with the conditions, but also by the people at large who have a vital interest in the proper care of our pauper sick.

In this connection, the seventh annual report of the Pauper Institutions Trustees for the year ending Jan. 31, 1904, is of interest. During the term of service of this board of trustees, the development of the medical side of the hospital had been going on year by year until at the time of their retirement from office it had attained a high rank as a well-equipped and well-manned institution for the care of the chronic sick. The feeling has grown that this institution should be regarded rather from the point of view of a hospital than of a mere refuge for the infirm, and that its future development should take place along hospital lines. Reference to the report demonstrates in striking fashion the correctness of this point of view.

During the year there were 847 admissions to the institution. Of these, 568 or 77.2%, went direct to the hospital. If such figures are fairly constant, and we have no doubt that they are, the attempt to regard the institution as an infirmary, merely, evidently cannot be maintained. The further statistics that 1,200 cases were treated in the hospital during the year, of whom 253 were hospital patients on Jan. 31, 1903, and that among the entire number treated there were 232 deaths during the year, are again evidences of the condition of chronic invalidism which prevails. The hospital for tuberculosis, established recently, has proved far inadequate to the demands made upon it. It will accommodate 51 patients, but on Jan. 31, 1904, there were 82 in the institution, naturally necessitating their classification with other patients, a plan which is altogether to be regretted.

The report of the visiting staff calls attention to the general medical work which has been accomplished during the last year at the institution, and insists upon the necessity of regarding practically the entire institution community as coming in the category of the sick. The need of a pathological building, the desirability of the installation of an x-ray apparatus, and the usefulness of a receiving ward for the hospital, are touched upon in this statement. The retiring board of trustees is deserving of the gratitude both of the medical profession and the laity, in having clearly seen the necessities of the situation and carried out those plans which looked toward a completer hospital development. That the work so inaugurated will be allowed to languish is not to be seriously entertained. The city needs a hospital of the first rank at Long Island if it is to maintain its traditions and keep pace with the admirable work done in other cities.

The *London Times* of June 6 refers to certain conditions at the Infant Asylum at Wanstead, a charitable institution supported by the public, and providing for upwards of five hundred children of both sexes. Not long since, for certain reasons not stated, the staff of trained nurses was dismissed from the hospital and adequate provision for the proper isolation of infectious cases was not carried out. In consequence of these circumstances, the consulting medical staff very properly felt called upon to resign on the ground that those arrangements it regarded as necessary for the health and well-being of the patients were

not inaugurated, and that therefore its responsibility for the occurrence of disease could no longer be borne. We state these facts, as quoted, simply to illustrate the very great desirability of perfect co-operation between the public, as represented by the management of such institutions, and the physicians who are and should be held responsible for their medical interests.

Wide as the differences of opinion may legitimately be as to the ways and means of the best management of our public institutions, it is apparent in this, as in all other complicated undertakings, that sympathy between the various departments should be maintained at the very highest possible level. This is perfectly possible, as examples everywhere show, and certainly the efficiency of an institution must depend in greatest measure upon the completeness of such co-operation.

In the city of Glasgow on May 15 of this year, 1,694 persons were classified in hospitals as dependent or pauper sick. The problem in Glasgow is, no doubt, absolutely similar to that in other cities, and there is every evidence to show that it is being thoroughly studied from various points of view, and that its solution must in great part be worked out on the basis of the hospital idea in the broadest sense of that term.

THE VALUE OF LEUCOCYTOSIS IN THE PELVIC AFFECTIONS OF WOMEN.

LEUCOCYTOSIS in the pelvic affections occurring in the female may be considered under three different aspects: First, as a diagnostic measure; secondly, as an indication or a contra-indication for surgical interference; and thirdly, as an indication in the prognosis. From his personal experience in the matter, Carmicheal in a recent and very able contribution to the subject (*Scottish Medical and Surgical Journal*, February, 1904) concludes that leucocytosis cannot be looked upon as an infallible sign of the presence of pus, and that it should only be taken into account along with other symptoms presented by the patient. In six cases of ovarian neoplasms, the leucocytosis varied and was not marked, appearing to be rather more directly in relation to the amount of inflammation present than to the malignant nature of the affection. In acute inflammatory lesions there was always a marked increase of the leucocytes with an increased temperature, but a leucocytosis is without value when no other symptoms are present.

A leucocytosis is of great importance in chronic processes. In lesions of the tubes the presence of a leucocytosis will give indications as to the presence of pus, the virulence of the bacteria, as well as the best operative procedure to adopt. If there is a high degree of leucocytosis with a marked tumefaction of the tube, palliative treatment, simple drainage or a vaginal operation is to be selected. When the leucocytosis is not marked and the tube not greatly enlarged the abdominal route is the one of choice.

In carcinoma of the cervix with extensive ulceration, a marked leucocytosis is often found, but under these circumstances the operative indications are governed by the local conditions.

After hemorrhage, for example, in cases of fibroids, a high leucocyte count may be found which would be rather a contra-indication for operation until the time when palliative treatment has reduced the number of leucocytes.

As to the prognosis, it is well known that a leucocytosis may be absent in cases of very acute appendicitis, and Carmicheal found it wanting in a case of puerperal septicemia. In infections, the absence of leucocytosis is serious, and if in a case of puerperal septicemia the general condition becomes worse, and there are indications that the organism no longer reacts against the infection, there is still time to operate in order to rid the patient of her focus of infection. When making a blood count one should never forget the normal causes of a leucocytosis, such as digestion, anesthesia, hemorrhage, purgation, etc., in order to avoid all possibility of error.

INTERESTING IF TRUE.

THE proverbial inaccuracy of birth weights leads to a certain legitimate skepticism regarding the truth of the statement which we quote in the following paragraph. Just why there should be so wide margin of error in estimating the weight of the new-born child is not always easy to appreciate, but that it should be greater than it actually is, is no doubt in a measure due to the natural pride of the parents. To be the mother of the largest infant on record is no doubt a worthy ambition, and possibly Mrs. Tasta, to whom we refer, was imbued with this idea. However this may be, we give the fact for what it is worth.

Mrs. Madelina Tasta, of the Italian colony in New York, is reported to have celebrated the Fourth of July by giving birth to one of the largest infants on record, its alleged weight being nineteen pounds. If this report is even measur-

ably trustworthy, it is especially remarkable for a first child, as the young mother is stated to be only eighteen years old.

The largest child delivered alive mentioned by Lusk is one reported by Waller, the weight of which was fifteen pounds fifteen ounces. Ramsbotham speaks of a fetus weighing sixteen and a half pounds, and Cazeau of one which he delivered by turning which weighed eighteen pounds, while in the *British Medical Journal* of Feb. 1, 1879, the birth of one weighing twenty-one pounds is reported. Dr. Robert Harris, the American editor of "Playfair's Midwifery," states that probably the largest fetus on record was that of Mrs. Captain Bates, the Nova Scotia giantess, whose husband was, like her, over seven and a half feet tall. This child, born in Ohio, was their second, and was lost in its birth, as no forceps could be procured of sufficient size to grasp the head. It weighed twenty-three and three-quarters pounds, and was thirty inches in length. Their first infant weighed nineteen pounds at birth.

MEDICAL NOTES.

Fourth of July Death List. — The *Chicago Tribune* announced on July 6 that the total number of deaths resulting from accidents on the Fourth of July was 52, and the number of persons more or less injured 3,049. Up to the time this report was made the death list this year was one less than that of 1903, and the number of injured 616 less. The result of tetanus cases, which are sure to occur in greater or less number, cannot yet be determined.

Tuberculosis at the Johns Hopkins Hospital. — It is announced that the Johns Hopkins University is about to undertake systematic work on the subject of tuberculosis. Aided by a gift of $20,000 from Mr. Henry Phipps of Pittsburg, a dispensary building is proposed, so arranged as to combine the treatment of patients with adequate rooms for investigation.

Dean of Medical School of University of Southern California. — Dr. Walter Lindley, the editor of the *Southern California Practitioner*, has recently been elected Dean of the Medical College of the University of Southern California. This Los Angeles school is now entering its twentieth session.

Physicians for Panama. — It is stated that about three hundred physicians are to be sent to the Isthmus of Panama to care for the health of the fifty thousand men who are to be engaged on the forthcoming work on the canal. For this work young and active men in robust health will be needed, and no doubt they may without difficulty be obtained.

Visit of French Physicians to London. — A number of representative French physicians are intending to pay a visit to London in October for the purpose of investigating methods of work and research in England. Arrangements for their proper reception are already being undertaken by the physicians of London. Such tours of friendly inspection among the medical men of various countries should most certainly be encouraged.

The New Vienna General Hospital. — According to the *Medical Record:* "On June 21, 1904, the Emperor of Austria laid the cornerstone of the new Allgemeines Krankenhaus, to take the place of the present famous building. The new hospital will in reality be a village of fifty buildings, and will contain every device and appointment known to medical science. It is the aim of the directors of this gigantic hospital to make it the finest, best and most completely equipped hospital in the world. It will be built upon one of the hills of Vienna, overlooking the present site, and the grounds will be much more beautiful than those of the present hospital.

BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon, July 13, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 40, scarlatina 15, typhoid fever 17, measles 29, smallpox 0.

A Bit of Newspaper Medicine. — The proverbial ignorance of the laity on medical matters finds some excuse when such statements as the following are possible, quoted from a local daily newspaper:

J. J., who became paralyzed and insane from the effects of a blood clot on his brain, attempted to commit suicide by shooting. The ball fired by him penetrated the affected part, dissipated the blood clot, restored his sanity, and it is believed he will entirely recover from his paralysis.

Commendable Emergency Work. — At the recent destructive fire caused by lightning in Charlestown, Lieut. W. C. Rucker, Past Assistant Surgeon, U. S. N., in charge of the United States Marine Hospital in Chelsea, and his assistants were upon the scene with their equipment a very

few moments after the fire broke out. It is said that they arrived and were at work caring for the injured before the arrival of the fire apparatus.

NEW YORK.

PUBLIC BATHS. — The first of a series of permanent public baths, to be erected and maintained at the city's expense, was opened on July 1 in William H. Seward Park, on the lower east side. The building, which is of brick exterior, with a liberal use of marble for interior appointments, cost with its equipment about $110,000. It is Ionic in its style of architecture, and consists of three stories. The first floor is devoted to the baths, and, allowing twenty minutes for each bather, it is estimated that at least 2,500 persons can be accommodated daily. The second floor, a special feature of which is a large loggia, supplied with comfortable chairs, is reserved for the use of women, especially those with young children, and two matrons will attend to their wants. This bath is absolutely free, even as regards soap and towels, the expense of which is to be paid for out of the maintenance fund. Similar buildings are to be erected in the DeWitt Clinton, Thomas Jefferson, St. Gabriel, and other small parks.

JUNE MORTALITY. — The mortality in the city during the month of June represented an annual death rate of 20.98, as against 21.70 in May and 16.95 in the month of June, 1903. One factor in the increased mortality, as compared with that of last year, is the epidemic of cerebrospinal meningitis which has prevailed. As compared with May, the effect of warm weather is strikingly shown in the decrease in the number of deaths from pneumonia and organic heart diseases; while, on the other hand, there is naturally a considerable increase in the deaths from diarrheal diseases. Among the diseases which showed a reduced mortality were the following: The weekly average of deaths from diphtheria and croup decreased from 47.25 in May to 42.5 in June; the weekly average of deaths from scarlet fever, from 25 to 15.25; from measles, from 38.75 to 21.75; from influenza, from 7.5 to 1.5; from typhoid fever, from 10 to 7.75; from pneumonia, from 173.25 to 69; from broncho-pneumonia, from 101.25 to 59.25; from acute bronchitis, from 39 to 23.75; from pulmonary tuberculosis, from 178.5 to 152; from Bright's disease and nephritis, from 126 to 104; and from organic heart diseases, from 102 to 70.5. There was a slight increase in the mortality from cancer, while the weekly average of deaths from diarrheal diseases increased from 48 to 131.5, and from diarrheals under two years of age, from 38.5 to 119. In the week comprising the last six days of June and the first day of July there were no less than 316 deaths from diarrheal diseases, as compared with 100 in the preceding week and an average of 55 in the earlier weeks of June. During the month there was one death from smallpox, the first since March.

The epidemic of cerebrospinal meningitis has continued to show a gradual decline. The deaths reported from it have been as follows:

In the week ending June 4 — 63.
In the week ending June 11 — 54.
In the week ending June 18 — 53.
In the week ending June 25 — 48.
In the week ending July 2 — 39.

WORK OF SUMMER CORPS OF PHYSICIANS. — On July 5 the summer corps of physicians of the New York Board of Health, sixty in number, commenced their annual house-to-house visitation among the tenement population, for the purpose of preventing illness among the children and relieving it when found. On the same date the regular trips of the St. John's Guild floating hospital to New Dort, Staten Island, were commenced for the season. The rules require that while in the boat each infant and child, unless special circumstances contra-indicate, shall receive a bath. For the older children salt water shower baths are employed. The "Helen C. Juilliard," the newer of the two floating hospitals belonging to the Guild, and the only one which will probably be used this summer, has been thoroughly overhauled and painted, and before commencing its trips was subjected to a rigid inspection. It is equipped with 600 new life preservers and with adequate life boats, rafts and buoys, while for fire protection there are six fire extinguishers, a heavy Worthington steam fire pump, and eight lines of fire hose attached to standpipes. The tug which tows the boat is also equipped with a powerful fire pump, and the crew is skilled in fire drill. The "Juilliard" has in all a working staff of forty-eight.

Obituary.

SAMUEL LEONARD ABBOT, M.D.

DOCTOR SAMUEL LEONARD ABBOT died July 1, at the age of eighty-six years. He graduated at Harvard college in 1838, in the class with James Russell Lowell and William Story, and from the Medical Department in 1841.

He was one of the oldest physicians of Boston,

and the last of that noteworthy group of practitioners connected with the Massachusetts General Hospital, a half century ago. He was the first physician to out-patients when the service was so small that a single physician could fill the position, and remained upon the visiting staff until disqualified by age. These duties of his public professional life he performed with uniform and conscientious devotion.

His private practice lay among the old families of the "west end." Rich and poor found in him a faithful and cheering counsellor, and there in quiet and shady Louisburg Square he continued to live and work until his death.

Dr. Abbot had that active interest in manifold directions which characterized the old-time member of our profession. In early days he was a zealous student of ornithology, and was long officially connected with the Boston Society of Natural History. He was a member of the American Academy of Arts and Sciences. For many years he was associate editor of the BOSTON MEDICAL AND SURGICAL JOURNAL. He was the oldest living member of the Thursday Evening Club, composed of representatives of all professions in the widest modern acceptation of the term, of merchants, capitalists, etc. He was from childhood connected with the First Church in Boston, and long one of its administrators.

He has passed away after a long, useful and gentle life, this conscientious, amiable physician, respected and beloved by all who knew him.

Miscellany.

DEATHS IN BATTLE DURING LAST CENTURY.

THE *British Medical Journal* makes the following statement of Professor Richet's estimate of the number of deaths in battle during the last century:

The genial and learned Professor of Physiology in the Faculty of Medicine in Paris, Prof. C. Richet, once wrote a novel and made a forecast of the probable condition of the world a hundred years hence. An ardent lover of peace on earth and an eloquent apostle and advocate of the doctrine of goodwill among men, Professor Richet has been "looking back" over the past century and reckoning the death toll due to wars during the enlightened nineteenth century. He estimates the grand total to be about 14,000,000, made up as follows: Napoleonic wars, 8,000,000; Crimean wars, 300,000; Italian war, 300,000; American Civil war, 500,000; Franco-German war, 800,000; Russo-Turkish war, 400,000; civil wars in South America, 500,000; various colonial expeditions in India, Mexico, Tonquin, South Africa, etc., 3,000,000. If to these who died in the "stricken field" we add the number of "broken" disabled soldiers, the widows and the children who suffered, we have indeed a huge budget of slaughter, a record of Christian activity that almost makes one despair. The new century seems to have started as if it intended to maintain the record.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JULY 2, 1904.

CITIES.	Population Estimated, 1904.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from				
				Infectious diseases.	Acute lung diseases.	Diphtheria and croup.	Cerebro-Spinal Meningitis.	Typhoid Fever.

Deaths reported, 3,469; under five years of age, 1,273; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,138; acute lung diseases 289, consumption 364, scarlet fever 20, whooping cough 14, cerebrospinal meningitis 43, smallpox 2, erysipelas 6, puerperal fever 11, measles 32, typhoid fever 48, diarrheal diseases 522, diphtheria and croup 76.

From whooping cough, New York 5, Chicago 2, Philadelphia 3, Baltimore 1, Boston 1, Worcester 1. From smallpox, New York 1, Philadelphia 1. From cerebrospinal meningitis, New York 39, Baltimore 2, Fall River 1, Brockton 1. From typhoid fever, New York 12, Chicago 4, Philadelphia 11, Baltimore 2, Pittsburg 11, Providence 2, Boston 3, Worcester 1, Lynn 1, Pittsfield 1. From erysipelas, New York 2, Philadelphia 3, Boston 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending June 18, the death-rate was 13.8. Deaths reported 4,029; acute diseases of the respiratory organs (London) 57, whooping cough 101, diphtheria 29, measles 186, smallpox 1, scarlet fever 25.

The death-rate ranged from 1.7 in Handsworth to 23.7 in Stockport; London 12.8, West Ham 10.7, Brighton 14.9, Southampton 6.5, Plymouth 14.2, Bristol 12.6, Leicester 11.6, Nottingham 15.5, Birkenhead 11.8, Liverpool 18.7, Bolton 12.5, Manchester 20.0, Salford 17.8, Bradford 14.8, Leeds 18.6, Hull 13.1, Sheffield 13.1, Cardiff 10.6, Rhondda 14.1, Wigan 14.1, Merthyr Tydfil 16.5, Walthamstow 7.5, Warrington 15.5.

METEOROLOGICAL RECORD.

For the week ending July 2, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING JULY 2, 1904.

J. MILLER, JR., assistant surgeon. Detached from the "Denver" and ordered to the "Kentucky."

F. A. ASSERSON, assistant surgeon. Detached from the "Kentucky" and ordered to the Navy Yard, New York, N. Y.

J. C. PRYOR, surgeon. Commissioned surgeon with rank of Lieutenant Commander, from March 3, 1903.

C. D. LANGHORNE, surgeon. Commissioned surgeon with rank of Lieutenant Commander, from June 9, 1903.

W. G. FARWELL, N. T. MCLEAN, C. T. GRAYSON, assistant surgeons. Commissioned Assistant Surgeons with rank of Lieutenant, junior grade, from June 28, 1904.

J. MILLER, JR., assistant surgeon. Orders to the "Kentucky," revoked; detached from the "Denver" and ordered to duty with the marine battalion on the Isthmus of Panama.

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING JULY 7, 1904.

PURVIANCE, GEORGE, assistant surgeon-general. Granted leave of absence for one month from July 1, 1904, on account of sickness. July 7, 1904.

KALLOCH, P. C., surgeon. Granted leave of absence for eight days from July 7. July 1, 1904.

MCINTOSH, W. P., surgeon. To assume temporary charge of the Portland, Me., quarantine station during the absence on leave of the medical officer in command. July 1, 1904.

CURRIE, D. H., assistant surgeon. To report to chairman of board of examiners, San Francisco, Cal., July 25, 1904, for examination to determine his fitness for promotion to the grade of passed assistant surgeon. July 1, 1904.

KORN, W. A., assistant surgeon. To report at Washington, D. C., for special temporary duty. July 5, 1904.

HOLT, J. M., assistant surgeon. To report to chairman of board of examiners, San Francisco, Cal., July 25, 1904, for examination to determine his fitness for promotion to the grade of passed assistant surgeon. July 1, 1904.

TROTTER, F. E., assistant surgeon. To report to chairman of board of examiners, San Francisco, Cal., July 25, 1904, for examination to determine his fitness for promotion to the grade of passed assistant surgeon. July 1, 1904.

MCLAUGHLIN, A. J., assistant surgeon. To proceed to Atlantic City, N. J., for the purpose of making a physical examination of certain keepers and surfmen of the Life Saving Service. July 7, 1904.

FOSTER, A. D., assistant surgeon. Granted leave of absence for seven days from July 8. July 6, 1904.

ROBERTSON, H. MCG., assistant surgeon. To proceed to Point Pleasant and Tuckerton, N. J., for the purpose of making a physical examination of certain keepers and surfmen of the Life Saving Service. July 7, 1904.

MCKEEN, F. H., assistant surgeon. Relieved from duty at New York (Stapleton) and directed to proceed to New Orleans, La., and report to the medical officer in command for duty and assignment to quarters. July 7, 1904.

SPANGLER, L. C., pharmacist. To report to chairman, board of examiners, Tampa Bay Quarantine, July 11, 1904, or as soon thereafter as may be determined by the chairman of the board, for examination to determine his fitness for promotion to the grade of pharmacist of the second class. July 1, 1904.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., July 6, 1904, for the physical examination of an applicant for appointment as Second Assistant Engineer in the Revenue Cutter Service. Detail for the board: Assistant Surgeon General G. T. Vaughan, chairman; Assistant Surgeon A. J. McLaughlin, recorder.

Board convened to meet at Tampa Bay Quarantine, July 11, 1904, or as soon thereafter as may be determined by the chairman of the board, for the examination of Pharmacist L. C. Spangler to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: Assistant Surgeon R. E. Ebersole, chairman; Acting Assistant Surgeon G. H. Altree, recorder.

Board convened to meet at San Francisco, Cal., July 25, 1904, for the examination of Assistant Surgeons to determine their fitness for promotion to the grade of Passed Assistant Surgeon. Detail for the board: Passed Assistant Surgeon W. G. Stimpson, chairman; Passed Assistant Surgeon Rupert Blue; Passed Assistant Surgeon H. S. Cumming, recorder.

APPOINTMENT.

DR. WILLIAM R. PRYOR, Professor of Gynecology at the New York Polyclinic Hospital, has been appointed Attending Gynecologist to St. Vincent's Hospital.

SOCIETY NOTICES.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION. — The Thirtieth Annual Session of the Mississippi Valley Medical Association will be held at Cincinnati, Ohio, October 11, 12, 13, 1904, under the presidency of Dr. Hugh T. Patrick, of Chicago. The headquarters and meeting places will be at the Grand Hotel. The annual orations will be delivered by Dr. William J. Mayo, of Rochester, Minn., in Surgery, and Dr. C. Travis Drennen, of Hot Springs, Ark., in Medicine. Request for places upon the program, or information in regard to the meeting, can be had by addressing the Secretary, Dr. Henry Enos Tuley, Louisville, Ky., or the Assistant Secretary, Dr. S. C. Stanton, Masonic Temple, Chicago, Ill.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. — The fourteenth annual meeting of the American Electro-Therapeutic Association will be held at the Inside Inn, St. Louis, Mo., September 13, 14, 15 and 16, 1904. The scientific sessions will be held only in the mornings, leaving the afternoons free in which to visit the fair.

RECENT DEATH.

ADIN HUBBARD NEWTON, M.D., M.M.S.S., died in Everett, July 7, 1904, aged eighty-seven years.

Original Articles.

A CASE OF MORAL INSANITY WITH REPEATED HOMICIDES AND INCENDIARISM AND LATE DEVELOPMENT OF DELUSIONS.*

BY HENRY R. STEDMAN, M.D., BROOKLINE, MASS.

On Oct. 30, 1901, J. T., a professional nurse, about forty-five years of age, single, and born in this country, was arrested on the charge of murdering Mrs. M. G. at Cataumet by poisoning, on the 13th of the preceding August. There was sufficient ground for belief that she had also fatally poisoned, within the preceding six weeks, an entire family of three persons who were related to M. G. by marriage. The duration of the last illness of Mrs. M. G. was not over sixteen hours. The symptoms, which were similar in all the cases, were those of narcotic poisoning. M. G. went unexpectedly into a somnolent condition from which she could not be roused, and coma and death soon followed. The relatives who, as it was believed, met death at J. T.'s hands were Mr. and Mrs. A. P. D., her father-in-law and his wife, and Mrs. H. G., on all of whom she had been in constant attendance from the first.

Mrs. D. died on July 4, after an illness of eleven days. The illness was characterized by intermittent coma, often deep; in the intervals, drowsiness with occasional rousing up and partial consciousness; pupils contracted, but not firmly, with dulled sensibility to light; on one occasion improvement with rationality, succeeded by profound coma and death.

Mrs. H. G. who died July 31, was ill ten days or two weeks, with similar symptoms. She became dull and stupid, "moped around the house, and finally went to sleep and never woke up."

Mr. D. died Aug. 9, after an illness of seven hours in which somnolence predominated, and complete unconsciousness rapidly supervened.

They had all been in good health before the appearance of these symptoms. The nurse had for years been on an intimate footing with the family, who were attached to her and regarded her as one of themselves. Her services were offered at some suggestion of hers or theirs regarding trivial ailments, real or fancied. She gave enemata freely, and often administered medicines in that way.

These short and fatal illnesses, so much alike and of such an unusual nature, occurring as they did, one after another, in the space of a few weeks, finally aroused suspicions of foul play, which naturally centered in J. T. who had nursed and dosed the victims, and had only summoned the physician when they were at the point of death. That she was well aware of the sentiment against her there is no room for doubt, as she was not only pointedly questioned on the subject by several persons but was actually told by a relative of one of the deceased that she was suspected of causing the deaths. Notwithstanding this, we find her in her old home only a fortnight later in L. in attendance on Mrs. B., an old lady and friend, who is suddenly and unexpectedly taken ill soon after J. T.'s arrival, and dies within forty-eight hours of the first appearance of a train of symptoms closely resembling those in the case of Mrs. M. G. The analysis by Dr. E. S. Wood, professor of chemistry at the Harvard Medical School, of the organs of four of the bodies revealed the presence in each of more than sufficient morphine to cause death. In the liver of the other body, that of Mrs. D., he found very distinct traces of morphine. It was the only one not embalmed, and as it had been buried nearly four months the organs were in an advanced stage of decomposition.

One of these persons held a note of J. T.'s to the amount, it is reported, of several hundred dollars. Small sums of money belonging to three of the others were missed after their deaths, but there is no proof of the truth of these charges. There was no suspicion of theft from the third victim, and in the search for a motive in her case a threat of exposure was advanced by the relatives. While Mrs. B. was in the midst of her illness a detective called at the house, and in the room below the sick chamber questioned J. T. at length about the deaths of her last four patients, ostensibly with the view of fastening the guilt of murder upon another person. Throughout the entire interview she was calm and self-possessed, showing no trace of anxiety and talking freely and pleasantly. She made no attempt to implicate others. Not long after this she told one of her friends that a state detective had told her that she was suspected of the crimes and must prepare to defend herself.

She remained here about a month, entertaining her friends, — in the meantime writing the physician of one of her Cataumet victims, "I have been taking my vacation and am willing to come back any time for a case." On Sept. 29, and 30, 1901, she made two attempts to poison herself, probably with morphine, the last an apparently determined one. An emetic given after an hour and a half was followed by return of consciousness. She gave later, as her reason for these attempts, that she was jealous and desperate because a man of seventy years, a connection of Mrs. T., was very attentive to one whom he has since married. As a final attempt to induce him to break off this intimacy J. T. wrote him, from the local hospital where she was immediately sent, an absurd and abusive letter in which she accused him of being "the father of her unborn babe."

After leaving the hospital she made a visit to some friends in a neighboring state, of which she has lately written: "I never even thought of the investigation about the murder while at A. until I was arrested. I was having a fine time out there. I don't think I ever enjoyed myself as I did that fall. There was a jolly lot of people there, and I had the kind of time I like to have. I remember perfectly well the detective reading the warrant and saying, 'I have come to arrest you for the narcotic poisoning of Mrs. G.,' and

* Read April 21, 1904, before Boston Society of Psychiatry and Neurology.

even then I cannot think it made much impression on me. The funniest thing about it was that I was annoyed because the detective insisted on remaining in my room while I was getting ready, and I did not think it was very gentlemanly." She left the house, on her arrest, with perfect composure and without the slightest remonstrance. On the long trip to the jail she was at first thoughtful, but later talkative and in good spirits. She talked freely to the officers about herself, and seemed entirely willing, then and at the jail, before seeing her counsel, to admit her guilt, and showed little or no realization of her situation, a condition of mind which she maintained throughout her imprisonment and trial. She was indicted for the murder of three of her Cataumet patients, but her trial was upon only one count, that of the murder of Mrs. G.

On March 3, 1902, about four months after her arrest, the prosecution and defence effected an arrangement whereby Dr. Geo. F. Jelly, Dr. Quinby and the writer were called upon to conjointly examine and report upon the mental condition of the prisoner with reference to her responsibility. Thus the question was practically submitted to a commission at law, which allowed the examiners free interchange of opinions and impartial sifting of all obtainable evidence on both sides. In fact, it resolved itself into a medical consultation on the diagnosis of a case of alleged disease. A more practical and satisfactory method, and one more in keeping with the principles of scientific inquiry, could not have been chosen, and its adoption by the attorney-general in such an important case would seem to be a long step toward abolishing, in criminal cases at least, the opposite and customary practice which has done so much to discredit expert opinion.

The evidence upon which our opinion was chiefly based was in part furnished by the prosecution and in part collected by ourselves. Since the patient's commitment other facts antedating her arrest have been brought to light, and are here introduced for the sake of uniformity and completeness.

Her original name was Honora Kelly. In 1863, when about four years of age, she and a sister were placed in a foundling asylum by her father, an eccentric man who drank hard to the time of his death. She has two living sisters; one, a respectable and capable woman some years older who corresponds regularly with J. T., the other, a chronic dement in one of our state asylums. A third sister was adopted but turned out of doors when found to have an illegitimate child. She led a dissolute life and died recently.

When about six years of age Honora was apprenticed to Mrs. T. on indenture papers, and took the name by which she has since been known. She was given a good education, proving intelligent and quick to learn. Mrs. T. brought her up as a daughter and she was "made much of" by the family. Until J. T. was a woman she was under good moral and religious influences, home surroundings and discipline and had good associates, but her incorrigible propensities for deceit, falsehood and trouble making, never absent from the first, proved too much to contend against, and her mother finally refused to let her remain longer in the family. Her impossible tales and her lies, often senseless and doggedly persisted in, despite positive proof of the falsity, are well remembered in the neighborhood.

At twenty-eight she began her career as nurse by four years of training and service in two general hospitals. There she showed much capability in the technical part of her duties. "She knew how to take good care of her patient but did not like to work." Although not of attractive appearance, she had a pleasant manner, and was wonderfully clever in ingratiating herself with such patients and physicians as she wished to please, and remarkably skillful in escaping the consequences of wrong-doing and in implicating others. Her hospital life revealed her earlier tendencies, but aggravated in form and more serious in results by reason of the greater opportunity for their exercise. Among the nurses, also, she made friends. One of them states, nevertheless, that she was looked upon as "queer" and "peculiar" by her fellow-workers because of her unfounded and absurd suspicions, tale-bearing, slanderous gossip and consequent mischief-making, as well as her pleasure in inventing fabulous tales. In several well authenticated cases she attempted, by charges afterwards found to be false, to procure the removal of patients from the institutions, and succeeded in two instances. In connection with one of these cases she wrote one of the patient's friends, who had met her only casually, a peculiar letter, stating that as he had made inquiry about her family (which he had not done), that she was quite willing to tell him that her brother was in an insane asylum. She then went fully into her family history. On the other hand, she is known to have prolonged the illness of favorite patients whom she wished to keep in the hospital, by reporting symptoms that did not exist and falsifying temperature records. In other cases she reported false temperatures for no obvious reason. During her term of service at one of the hospitals many articles were missed: sums of money, stationery, aprons, uniforms, etc., and she was suspected of stealing them, but her friends spoke so well of her and she was so adroit that the suspicion went no further, in spite of the evidence against her. In administering medicines she was extremely reckless and frequently gave larger doses than had been prescribed. Even at that time she was often heard to say that there was no use in keeping old people alive (a favorite sentiment with her since). She was also fond of asking about poisonous drugs and their antidotes.

In view of the long wake of sudden and mysterious deaths of patients, which has followed this woman throughout her career as a nurse, the following incident of her hospital life is at least worthy of passing notice. Miss D., a nurse, who had a slight illness, was put under her charge by day and was soon seized with sudden and extreme collapse. By much effort she was brought out of danger in the course of the night. When J. T. came on duty the next day the same symptoms reappeared. Another nurse was put in charge and the patient recovered. Some time afterward J. T. asked a head-nurse if she had heard that Miss D.'s condition had been due to poison.

She was at that time, and has often since been, suspected of the opium habit, because of her strange conduct. This is of course possible, but careful inquiry, as well as long observation of her at times when such a practice if previously indulged in to a great extent would have been revealed in the characteristic symptoms which follow sudden deprivation of the drug, have failed to show any such addiction. More-

over, her general conduct has been the same or more marked in situations where opium-taking was impossible. No tendency to sexual immorality or to drinking habits was ever noticed in her so far as we can learn.

She was discharged from both hospitals, in one instance just as she was about to graduate from the training school.

On leaving the hospital she took up private nursing in which she was for many years very successful, inspiring certain families, not a few of them of high social position, with confidence in her skill and affection for herself, in spite of caution from physicians who knew her record. She was "greatly liked and trusted" by one family who unsuspectingly employed her after the death of one of their number at her hands. Experienced and able physicians recommended her for a time on account of her capability. Her own friends who know her better speak of her jealous and vindictive nature and bad temper. Her conduct was considered "strange" by not a few — just in what way they cannot specify. As to her propensities for falsehood one person reports: "She had an extraordinary facility for inventing lies and remembering the lies that she told others." Another: "She is a constitutional and clever liar, but I did not find it out until two years ago." Her passion for trouble-making for its own sake, by carrying tales true and false and insidiously fomenting enmities, for no apparent reason, though far less readily and generally realized than when she was at the hospital, came gradually to light. She borrowed money from patients or their relatives which she never repaid and, although she earned a good living, had many debts, which, however, gave her little concern. Occasionally, small sums of money and articles of clothing disappeared where she was employed, but she was rarely suspected and never detected in theft nor, to our knowledge, directly accused of it. Accepting her guilt in this respect as proven, however, the fact that, except in a few instances, they were all petty thefts, and that in many cases nothing whatever was missing, plainly shows that money gain was not a controlling motive for her homicides. She undoubtedly prolonged some cases for profit, but on the other hand cut short many that might have proved equally lucrative, by poisoning the patient. She set four fires, but gave the alarm and helped vigorously to put them out. Two were set in the same house in order to frighten a nervous patient and retard her improvement. The others occurred in cottages of her friends.

Her general conduct toward the end of her career as nurse is suggestive of increasing demoralization. Her stories grew more sensational and preposterous. She caused, for example, some consternation by an utterly baseless report of a severe epidemic of typhoid in a neighboring seminary. She repeatedly maligned physicians who had employed her to other physicians and to patients, and even criticised the method of treatment in the presence of physician and patient. In spite of this, she retained to the last a number of friends who thoroughly believed in her.

We have also been able to satisfy ourselves that to crown this career of crime and disordered conduct J. T. committed 20 homicides, 12 of which she admitted at the time of our examination. While in jail she made a list of 31 of her victims, giving names and addresses or other means of identifying them. Her statements regarding the 20 homicides are abundantly verified in 4 by the character of the symptoms and by autopsy; 12 are sufficiently proven by careful accounts of the train of symptoms magnanimously and freely given the writer by the attending physician in each case, which were in every instance but one characteristic of narcotic poisoning, and which they now agree to have been the cause of death; and 4 have been fully, and we believe faithfully, described by immediate relatives. Of the 11 deaths reported by her, above this number, 4 are yet to be investigated, but seem suspiciously like the others in causation; in 2 the whereabouts of the family are now unknown; while in 5 there is too much uncertainty as to the precise cause of death to warrant including them among her victims. Space will not admit of further description of these cases than has already been given. The manifestations were strikingly similar. All but one of the cases — in which strychnia was plainly the cause of death — showed all or most of the following symptoms: drowsiness, full, slow pulse, contraction of pupils, stertorous breathing, cyanosis and slow respiration. A not infrequent feature was the subsidence of the coma for one or more intervals, and the patient's return to full or partial consciousness until finally put to death. A number of her victims were patients of one of her chief benefactors and includes one of his connections.

Among her effects a much-worn textbook on poisons was found which fell open at the chapter on opium.

At our first interview at the jail, she seemed for a time somewhat serious and distrustful, but soon became at ease and talked freely and volubly. She appeared quite indifferent to her situation and seemed to regard our visits chiefly as pleasant breaks in her monotonous life. Her talk was more or less rambling and rather irrelevant. Her utter mendacity and disposition to speak slurringly of even her best friends and to make accusations against them, almost without exception — to praise one minute and blame the next — was very marked. We therefore soon found that we should be obliged to depend largely for our opinion upon facts obtained from others, accepting as true only such of her statements as were corroborated by reliable evidence.

She told many tales which we knew to be sheer inventions, among them, a story of her parentage, her alleged father having in reality lived in China for two years before her birth; another, of her horror of the dead which was so great that she sometimes fell senseless at the sight of dead bodies, even those that had died a natural death, the fact being that she had often laid out bodies with her own hands as a matter of course. Her attempts as suicide she narrated with glee, but admitted that the last was a serious one, and for the most part adhered to her story that jealousy had prompted them. She also stoutly denied that she had ever stolen anything or been dishonest in money matters, although admitting that she had failed to repay loans of money and that she had always been slack and "mixed up" in money affairs. At first she denied also that she was guilty of the homicides with which she was charged, but finally, and by no means unwillingly, confessed (although advised not to incriminate herself) that she had poisoned twelve patients and had made two unsuccessful attempts to poison others. She also admitted that she had set four fires, two of them at the residence of a patient under her charge. She told of the deaths with calmness, adding eulogistic remarks. The poisonous agent employed was, according to her story, always morphia, occasionally combined with a fatal dose of atropia. She could not remember the details in all cases because, as she remarked, "poisoning had become a habit of her life."

The facts: first, that her favorite method of ad-

ministration of the drug was in Hunyadi water or by enemata because the drug could in these ways be given without the knowledge of the patient; second, that when possible she did not summon the physician until the victim was moribund; and finally, that she sometimes so combined drugs in kind and proportion that their resulting effect was an unusual and perplexing set of symptoms, made it most difficult and in some instances impossible for the physician to ascertain the true nature of the patient's illness. A request for an autopsy by the physician, moreover, invariably met with refusal through J. T.'s vigorous opposition to the suggestion. This accounts in large measure for her long immunity from detection, and it seems probable that if she had not, in her increasing mental demoralization, so far abandoned herself to her craving for poison-giving as to put to death with the same drug or drugs four patients in one family within forty days, many more victims might have been added to the list.

In planning and carrying out her homicidal acts she was, she asserted, always calm and clear-headed. After administering the poison she always experienced great relief and went to bed and slept soundly. In one case she took to bed with her the child of her victim after administering the fatal dose [a fact], and in another she lay on the bed with the patient whom she had just poisoned "and had a long sleep." When it was too late to undo her work "she would work like a Trojan to save the patient," according to her statement, although in one case, at least, she took this opportunity to repeat the dose and make sure of her victim. In two instances she claimed to have been seized with compunction, and left the case after sending for another nurse. One of the patients was saved in consequence. For much of the time during the interviews she manifested a lack of seriousness and often a levity which was in marked contrast to what was to be expected of one who had been brought to confess so many heinous crimes. She understood clearly that she had done wrong, but did not manifest the slightest sign of remorse for her crimes, not, as it seemed to us, through any spirit of bravado but for the reason that she did not comprehend the enormity of her acts; she professed total indifference as to the outcome of her trial except that she preferred the prison to the asylum. Electrocution apparently had no terrors for her. "When I try," she said, "to picture it, I say to myself, 'I have poisoned M., my dear friend; I have poisoned Mrs. G.; I have poisoned Mr. D. and Mrs. D.' This does not convey anything to me, and when I try to sense the condition of the children and all the consequences I cannot realize what an awful thing it is. Why don't I feel sorry and grieve over it? I cannot sense it at all."

The question as to what prompted her acts was the signal for the shameless recital of a story of sexual excitement occurring in the presence of a dying person, as the motive — a statement which was all the more startling by reason of the absence of sexual immorality from her history, so far as could be ascertained. For a time we were of the belief that irresistible sexual impulse might be the real explanation of at least some of her acts, but on further examination, her representations as to the nature of this impulse and the conditions attending it were found to be so conflicting and so at variance with any known form of sexual perversion that feigning was suspected, and at the last interview, she admitted, as stated in our report, that she did not know why she killed these people, and that it was not from desire to experience sexual excitement. It was finally apparent that the story was a pretense throughout, concocted, and most unnecessarily as it happened, in order to prove her insanity and irresponsibility by reason of irresistible sexual impulse. There seemed to be a nearer approach to the truth in the statement that for at least the year past she had been tempted to do all sorts of criminal acts, and during the preceding summer especially, she had "let herself go." Among others she had strong impulses to set fires and could get no relief from her feeling of uneasiness but by yielding to the temptation. It is a fact that when once they were started, however, she worked her hardest to put them out. She finally said, in regard to her homicides, "I seem to have a sort of paralysis of thought and reason. Something comes over me, I don't know what it is. I have an uncontrollable desire to give poison without regard to the consequences. I have no objection against telling my feelings, but don't know my own mind. I don't know why I do these things." The last statement carried an air of truth with it in the manner of its telling and seemed to accord well with her general mental condition.

So far from having delusions of enmity or persecution, she spoke of most of her victims as her friends, and denied any hostility on either her side or theirs. In fact, all our efforts failed to reveal anything of the nature of delusion or hallucination in her mental condition at any of the interviews. Her behavior also was the opposite extreme of that of most patients with concealed delusions, whose reticence and distrust are marked features.

The main points in the summary of our opinion as to the prisoner's mental condition, which concluded our report to the attorney-general and counsel for the defence, were in substance as follows:

"1. The prisoner, J. T., comes of a family in which intemperance and mental weakness and disorder are prominent disease features.

"2. Her utter lack of moral sense has been evident from childhood in her incorrigible proclivity to falsehood, dishonesty, mischief-making, general unreliability and probable theft. The good moral, mental and religious training which she received in her youth resulted in no modification of her character, and were practically thrown away on her in that respect.

"3. Her moral insensibility is further apparent in the absence of sense of fear before, during or after the commission of her crimes, and of remorse, sorrow or genuine affection at any time. This defect is even more forcibly shown by the fact that her chief victims were her especial friends.

"4. Her lack of any appreciation of her situation, her levity under such circumstances, and her inability to realize the enormity of her deeds are strong evidences of mental weakness.

"5. That an irresistible propensity propelled her to crimes of arson and murder is shown by the great frequency and variety of such acts and her continuance in them, regardless of consequences.

"6. There is an absence of any apparent motive for her criminal acts in some cases, and inadequacy of motive in many of the others. This is shown in the total lack of evidence of pecuniary gain or satisfaction in revenge as a rule, except minor thefts and transient enmity. These would

be powerless with sane criminals as incentives to habitual homicide.

"7. The prisoner's disease-history and present mental state correspond with a well-recognized form of mental disease of a moral type due to congenital degeneration, in which there may be little or no intellectual disturbance that is apparent to the ordinary observer.

"Therefore, we are of the opinion that she was insane and irresponsible at the time of the homicides with which she is charged, and is so now; that, her disease being constitutonal, she will never recover, and that if ever at large again she would be a constant menace to the community."

The salient features of the case which indicated more especially irresponsibility were: lack of moral understanding, of natural feelings and of the ordinary motives for conduct including criminal acts, also the general absence in her of sufficient self-control to restrain her from crime, and her disregard of consequences as shown, for example, in continuing to poison patients in full knowledge that her guilt in other recent cases was suspected; by her desire to confess her guilt at the outset; her indifference to her fate, etc. These facts seemed to us to evidence her inability, both to help doing what she did and to be affected by punishment, conditions which are the best tests of accountability.[1]

The results of the anthropometrical measurements and physical examination of the patient by Dr. H. W. Miller, pathologist of the Taunton Insane Hospital, are as follows:

Physical examination. — Height, 5 ft. 3 in.; weight, 166½ lbs.

A well developed and well nourished woman. Hair black, streaked with gray. Complexion somewhat sallow.

Craniometric examination. — Circumference of head, 51.8 cm.; antero-posterior diameter, 17.8 cm.; greatest transverse diameter, 13.6 cm.; cephalic index, 77.6 cm. (slightly dolichocephalic); naso-occipital arc, 31.5 cm.; bregmato-lambdoid arc, 11.8 cm.; binauricular arc, 31.5 cm.; binauricular diameter, 11.8 cm.; facial length, 11.7 cm.; mid-frontal diameter, 13.5 cm.; breadth between pupils, 6.6 cm.; length of ears, right, 6.4 cm.; length of ears, left, 6.5 cm.

These measurements are all well within physiological variations.

Ears, detail well defined without stigmata.

Eyes, brown, palpebral fissure of normal width. No limitation of normal field.

Palate, low and broad but symmetrical.

Nose, no deviation or anomaly of the nose.

Teeth, false set in upper jaw, those in lower jaw regular.

No facial asymmetry.

Extremities: Symmetrical. Forearms, 40.2 cm. from elbow to tip of middle finger. Middle finger, 10 cm. on both hands, last phalanx of thumb 3 cm. on both thumbs. The little finger on each hand is flush with the last joint of the third finger. Finger nails normal.

No general body anomalies.

Special senses: Hearing acute; smell and taste normal; sight unimpaired; color sense keen.

General sensory condition: Examination of tactile, pain, pressure, and muscle sense offers no abnormality.

No errors of motility.

No trophic disturbances.

General feeling of well-being.

Reflexes: Show nothing of significance. Knee jerks sharp, normal plantar flexion, pupils equal, regular, react promptly, directly, and consensually.

A few tremors of tongue and extended fingers were present at time of examination but were transient.

Respiratory and circulatory systems reveal nothing of note.

Abdominal organs healthy.

Menstruation irregular for two years (every two weeks). Previous to that every fourth week.

Whatever view may be taken of this remarkable case, there can be no question that the moral monster thus far depicted is a striking illustration of so-called moral insanity, a condition described in most works by recognized authorities, from Pritchard to Kræpelin and Wernicke, as a probable form of mental disease or defect. Its existence as a definite morbid condition has been repeatedly questioned, and its name criticised as inadequate and incorrect. "Moral insanity," however, has so far held its own that all alienists of to-day recognize that the term means a certain condition or kind of mental abnomality which is *sui generis*. It fits no other form of mental unsoundness. The progress of psychiatry has seen so many nosological terms discarded that it is remarkable that "moral insanity" should remain and flourish, thus demonstrating its practical utility as a term and its real value as a morbid mental condition. "Moral imbecility," a more accurate designation in some respects and in use by certain authors, apparently has not been found sufficiently descriptive of every grade of moral lunatic to secure general adoption. The true understanding of moral insanity has been greatly obscured by confounding it with purely symptomatic conditions, syndromes and stages of other forms of insanity; for example, the moral obliquity unaccompanied by apparent intellectual perversion which sometimes occurs as a distinct stage of dementia precox, or as an equivalent of the "maniacal" phase of manic-depressive insanity, or as the prodromal stage of general paresis.

Moral insanity belongs to the group known as insanities of degeneration, and is better termed degenerative insanity of the moral type. It should be exclusively reserved to designate a congenital, primary, constitutional and permenant mental condition affecting the moral nature and unassociated with *evident* intellectual impairment. These patients have good memory and understanding, ability to reason and con-

[1] The ability to discriminate between right and wrong as the sole test of responsibility fails in this case for the same conclusive reasons that have rendered it valueless in a great many others, and have caused it to be rejected by all alienists and most jurists of to-day. It takes no cognisance of the power of personal restraint and inhibition. An insane person, as all psychiatrists know, may know right from wrong in the abstract, may understand that a certain act is unlawful and wicked, but may be unable to control himself through weakened will power (the result of hereditary defect or disease), or when goaded to desperation by persistent delusions and hallucinations. "In fact, the cases of insane criminals in whom there is no knowledge of right and wrong or who do not know the nature and quality of the acts they commit are very few indeed."— (McPherson.) It was one of the highest legal authorities of England, Lord Chief Justice Cockburn, who declared twenty years ago that the power of self-control when destroyed or suspended by disease was an essential element of responsibility.

trive, much cleverness and cunning, and a general appearance of rationality, coexistent with very deficient control, absence of moral sense and human sentiments and feelings, perverted and brutal instincts, and propensities for criminal acts of various kinds which may be perpetrated deliberately and cleverly planned, yet committed with little or no motive and regardless of the consequences to themselves and others. This latter point is important as indicative of a perversion of the fundamental instinct of self-preservation (Kellogg). In their general conduct, also, these individuals are rarely governed by the same motives that govern sane people, whether criminals or not, and it is often difficult to see what the motive is. As Esquirol truly says, "crime is a means for the criminal and the end for the lunatic." They commit crime for crime's sake. In J. T. most of the classic manifestations of the disease are typically and faithfully reproduced. That none of the physical stigmata of degeneration should be present is noteworthy but not exceptional, as Lombroso,[2] for example, finds anomalies of the cranium and physiognomy absent in 58% and 64% of moral lunatics, respectively. Of that distinctive and negative feature of the disease, the almost complete absence of intellectual impairment, Hack Tuke[3] goes so far as to say, "It is perfectly certain that it may be practically impossible to detect the intellectual flaw, and yet a physician may be driven to decide that a person is insane," and it is a recognized fact that, while a few of this class fall short of the average individual in intelligence, many are fully up to it and a limited number even surpass it.[4] Others urge, and our experience inclines us to agree, that careful investigation will always reveal intellectual involvement in genuine cases, sooner or later, and such patients certainly share some traits in common with the imbecile; witness their imperative and characteristic propensity, which seems to be a necessity from which they cannot escape, for telling purposeless lies and, like children, inventing fabulous tales. This is marked in J. T., but still more in this line of mental defect is her innate and irresistible bent for trouble and mischief-making which she finally carried to such an extent as to deliberately alienate her friends and benefactors among physicians — a weak-minded senselessness of conduct which showed fatal disregard of her own interests. If her friends were blind to her glaring faults and dangerous propensities it is hardly to be wondered at that they should fail to recognize that underlying "intellectual defect [in moral insanity] which," to quote Westphall, "is of a peculiar kind, is often concealed under a mask of perverted moral sense and requires time and patience on the part of the physician for its detection." J. T.'s fundamental intellectual weakness is further and strongly emphasized in her hospital history, as will be seen.

[2] "L'Homme Criminel." (Tr. from the Italian.) 1895. Vol. ii, p. 8.
[3] Dict. Psychol. Med., p. 814.
[4] McPherson, Mental Affections, p. 310.

But in what respect this case and others of its class differ from mere criminality is, of course, the main question. We can, at the start, readily eliminate the occasional criminal, the criminal by passion, the habitual, professional criminal; but to differentiate between the morally insane and the instinctive criminal, especially in the light of Lombroso's exposition of their analogy, is a difficult matter. It is this question that is and always will be a battle ground for the criminologist, the alienist, and the jurist, in spite of Lombroso's conclusion that both views are right and that they are one and the same thing. To our mind the very term implies a mental flaw, for what is instinctive criminality but perverted instinct, the very nature of which has made these persons lifelong enemies to society, and has rendered impossible a natural manner of feeling and acting, to the extent that in spite of good education and environment, habitually wrong conduct and actual crime become right to all intents and purposes and the ruling principle of life? It seems to us to resolve itself into a question of degree, and if Lombroso and his school should gauge instinctive criminality by the proportionate extent in each of these individuals of ordinary crime and culpability on the one hand and of mental defect and perversion on the other, wide differences would certainly appear which would compel them to classify many as indubitable criminal lunatics, and others as mere criminals, leaving an intermediate or borderland class whose condition cannot be satisfactorily differentiated. This is very evident in the enumeration by the great criminologist of many and marked symptoms which he admits that subjects of moral insanity share with those whom he acknowledges and classifies as insane criminals.

No absolute rule can be laid down by which we can differentiate between moral insanity and moral depravity, and there is no other disease in which the study of *ensemble* of its manifestations is so important. One may single out separate acts or sets of acts of a subject of moral insanity, and see in them only the manifestations of ordinary criminality. It is only when these are viewed in their entirety and in relation to the heredity, environment, education, social status, mental and physical organization and disease-history of the individual himself that we can decide how far his acts are under his control, and whether or not he is insane and irresponsible. It would be as questionable to label and treat as insane certain of the least pronounced subjects of this class as it would be wrong, both ethically and scientifically, to stamp as merely culpable criminals and to send to prison the extreme and typical ones like J. T. The former, whose condition approaches more nearly the borderland of sanity, are for that reason more susceptible to punishment and other incentives to right conduct. They bear prison life well and are none the worse for the discipline. The well marked, distinctly pathological cases, however, are for the most part turbulent, crafty and

unmanageable in the extreme, cannot be affected by punishment, greatly interfere with the discipline of others and are the despair of prison officials. Because of their defective control and susceptibility to criminal impulses, the associations and punitive measures of the prison also tend to make them deteriorate faster and to grow more intractable. The ordinary hospital for the insane is equally unsuitable for them, as they unsettle and excite their fellow patients and interfere with their management and improvement. Besides, association with criminals adds another terror to insanity. The special asylum for the criminal insane is, therefore, the only proper place for them, and it is still another argument for their insanity and irresponsibility that every criminologist advocates such confinement for them with this, the worst, class of the insane. There is, unfortunately, no special provision in Massachusetts for the care of female criminal insane, as their number is so small.

On June 3, 1902, J. T. was tried and found not guilty by reason of insanity, and thereupon committed to a state insane hospital for life. Her attitude at the trial was more that of an interested and appreciative spectator than of a prisoner on trial for her life.

Through many visits to the patient during the past two years and free access to the records of the Taunton Insane Hospital where she is confined, we have been able to follow her case which has undergone a striking development, as will be seen.

On her admission she talked freely about herself to the hospital physicians and, although she showed her inborn tendency to deceit and falsification in many ways, the fact that she had no longer anything to gain by misleading others with regard to her mental condition gives a certain weight to the most consistently maintained of her statements. She reluctantly acknowledged, as she does to-day, that she poisoned 31 patients. She would not say that she was not insane but wished to know what her insanity consisted of. "I don't appear like these other patients. I can read a book intelligently, I don't have bad thoughts, so I don't see where moral degeneracy comes in." When asked if she had noticed any change in disposition in recent years she said, "No; I feel absolutely the same as I always was. I might say I feel hilarious, but that may express it too strongly." As to the feeling of fear, she replied, "As far as I have any knowledge of that feeling, I never showed it. I cannot recall any time that I was frightened. I used to be the wonder of my mother. I have never felt it throughout this affair." She has certainly never been affected except pleasantly by sudden explosions or threats of patients on the wards from the first.

During the first year of her life at the hospital she was, as a rule, sociable, quiet, cheerful, amiable and spasmodically helpful, and spent much of her time in reading. The change from the seclusion of the jail to the more active life of a large hospital ward interested her, and the air of discipline was effective in temporarily repressing her tendencies. In this period she grew fat, was in excellent physical condition, and wrote her sister: "Just think, I've been here a year and find myself fond of the people and warmly attached to the place in some ways. Yes, we are well cared for, kindly and considerately." She soon developed a fondness for the company of the patients, especially the most demented, in preference to that of the nurses.

The following statement by Dr. J. P. Brown, the Medical Superintendent, is the hospital record of April 22, 1903, about a year from the time of her commitment. It practically represents the opinion of the entire medical staff as to her condition at that time:

"My study and observation of J. T. since she has been in the hospital gives me the opinion that her mental disease should be classed as moral or affective insanity. She seems to me to be wholly devoid of moral sense, or a clear apprehension of what is right or wrong as to her relations to other people or to society. In all my conversations with her respecting the homicides, which she freely admits, she has expressed no remorse, regret or sorrow for any of them, but rather a sense of pride and satisfaction that the number was so large as to give her distinction above all other poisoners whose histories are known.

"This lack of pity and sorrow for others in trouble or distress has been evident whenever any difficulty has occurred on the ward between patients, or between a nurse and patients. At such times she has manifested a good deal of glee, and laughed like a silly child, but never has expressed any sympathy or pity for the patient or person in distress or trouble. Trouble or pain for others seems to excite in her merriment and joy instead of sorrow.

"In her association with other patients she has exhibited a special fondness for the demented, and especially for one who has openly practiced self abuse; and once she got into bed with her after the patient had been put to bed for the night.

"In speaking of the homicides, she says that at the time she committed them she was not conscious of committing any crime or doing any wrong for which she should justly be punished; that the thought of doing wrong did not enter her mind, and gave her no concern whatever; and at the present time she apparently has no comprehension that the decree of the court in committing her to the hospital was right and just, and must be obeyed; and she asks for her freedom as though it could be granted on the same basis as that of any other patient.

"Recently, during the past three or four months, she has seemed more moody and emotional, either depressed or exhilarated at short intervals, and has exhibited less self-control, and with it she gives one the impression that her mind is weakening, and that she has less mental grasp of past and present events, and of her relation to her surroundings. Of this she seems to be painfully conscious herself. She has been observed to be laughing immoderately to herself, and when it is noticed by others she blushes as though she would conceal it, and seems confused.

"This weakening of her mind as time goes on is what is to be expected, and will probably continue. In every case of moral or affective insanity there must be more or less impairment of what are called the intellectual faculties in distinction from the moral, especially reason, and judgment to decide ethical questions presented to the mind, otherwise the moral obliquity and perversion would be controlled, and the criminal act averted.

"From my examination and observation of her since she has been under my care, and my knowledge of her previous history as made known to the court before her sentence, I am of the opinion that she is

insane and irresponsible, and that her mental disease, resulting as it probably does from ancestral vice and degeneracy, which her family history so far as known clearly indicates, is incurable."

Even at this time an undercurrent of suspicious thought came to the surface in doubts of the intentions of people toward her. She even wrote her sister in Chicago, "Sometimes it strikes me you are one of the gang. If you have fooled me also I shall say d—n. Oh d—n anyway."

Her complete indifference to the character of her surroundings, her frivolous talk, contradictory sentiments, frequent, causeless laughter, open pleasure at the trouble of others, glee at situations of obvious personal discomfort to herself, and general and utter lack of more than occasional seriousness at her situation, present and future, or actions in the past, show most plainly a dominant tone of mental weakness such as is only to be found in the imbecile. This is well shown by extracts from her letters: "I've had a real good time in the sewing-room for the past two days. I never can say that I like to do a thing until I get some fun out of it, and I really had quite a lot of fun. I suppose it has been here [in me] ever since I have been here, but I haven't seen it. . . . Truly, I had a great, good time at the Barnstable jail after the first ten days, even then I did not have a bad time." June 28, 1903, referring to an incident when on a visit to a friend: "It has left me rolling on the floor [with laughter]. I begin to feel like rolling on the floor now. I like to feel that way. I am having a big time, big" [in the sewing room]. March 8: "Don't ever ask me in your letters what I mean by what I write, I don't know myself — I'm talking through my hat. Nellie told me once that you said I made you dizzy when I got to talking and laughing. I laugh now, Mary. I nearly bust myself laughing this past week. I don't like the locality I live in either." July 8, 1903, after greatly disturbing the ward at night with a violent fit of screaming for no obvious cause: "I meditate and praise and pray all the time, and shall be ready at the end to take vows and become Mother Honora of the Seven Wounds." In one of her thoughtful moods she writes, "I do grieve to be in this state, I do, when I have thought force enough to think it out. When I am discontented I ask myself what I want and I don't know. A change of any kind seems torture to me even to think of and why I want to live this way I don't know. . . . Never mind, Mary, the fact remains that I have had a bully time in life in spite of everything." "I never feel that I am having a real good time when I'm behaving." Oct. 4: "I am still furnishing material for the drama of the 'unpopular lady.' I do wish I could behave myself for it all tires me so now, but I shan't probably till my last breath."

By December, 1903, she had become generally antagonistic toward all about her, as well as highly suspicious and irritable. She wrote voluminous tirades against the hospital and its management, treatment of patients, etc., making wholesale and absurd accusations and denunciations, some of an entirely delusional nature. She writes her sister, for example: "Do you know, the supervisor put some poison in my tea. A patient saw her and told me and I didn't touch it. The lady heard the supervisor say she had fixed J. T. this time." Apropos of special diet offered her she writes, "No, I thank you, Dr. Brown, I will stick to bean soup and keep safe above ground and out of Dr. Miller's [the pathologist's] hands. Some steak strikes some people right. This steak is sure death." Again, in a letter to her former counsel, she speaks of him as one of the "gang" who is managing her case, all the physicians and nurses of the hospital being included. She continued to write in this strain although told that such letters would no longer be forwarded. Dr. Brown also reports the following statement made to him by the paitent: "I don't wish to associate with the low and vulgar people that are employed in the sewing room. They talked about me before the other patients in a low and vulgar manner." She then described a revolting scene, impossible on its face, as enacted by the two employees in charge, self-respecting, modest women, and gave a circumstantial account of talk and actions on their part of the vilest kind, in a manner highly suggestive of delusions of persecution and hallucinations of hearing. At this time, also, she is reported to have grown very neglectful of her personal appearance, even having to be told to wash her face. She had become very abusive to the nurses, defying their authority and inciting patients to do the same, going so far as to shout to a melancholic whom the nurse was trying to feed, not to eat the food as it was poison. Her physical condition had fallen off greatly. She had lost fifty pounds in weight in a few months, in consequence of her refusal of food because of false belief in regard to it. Owing to her weak condition she was removed to the infirmary. There she became more disturbed, as well as destructive and dirty in habits, enraged and somewhat violent, threatening to kill her nurses, etc. By February, 1904, she was greatly emaciated, having lost over eighty pounds, or about half her normal weight, and was so weak that forced feeding with the tube was resorted to for several days, since which time she has eaten voluntarily, but just enough to avoid being fed again. The artificial feeding was only resorted to after persistent persuasion and every possible measure to induce her to eat had been tried, including special articles of diet from the superintendent's table. A thorough physical examination revealed no evidence of bodily disease.

On a recent visit, March, 1904, she was found by the writer in good spirits, talking volubly and aimlessly at the nurses. She began at once on a tirade against the hospital, its officers and all its belongings. She insisted that everything was "rotten," that the meat was "embalmed" beef, etc., etc. She persisted in these complaints after being told that we had just eaten the dinner provided for her which we found nutritious and palatable. Everything was filthy, she said, even the brick walls which must be "saturated with the filth of years"; the water supply (which is taken from an artesian well) was "polluted with sewage"; the vegetables were "rank poison." She spoke rather anxiously about a general feeling of numbness, and asked what was the cause of it. She was entirely inaccessible to explanation, argument, or even positive proof as to the impossibility of her statements. Occasionally she would burst out unexpectedly with peculiar and piercing shrieks of laughter which would seem impossible to one in her weak condition.

Many of her indiscriminate and senseless charges seemed to be rather the expression of an insane malignity toward everyone than the outcome of genuine belief that they were true. But we were, at the same time, convinced beyond a doubt that she was also suffering from strong and genuine delusions of persecution by poisoning, because her belief in this regard so consistently influenced her conduct that her refusal of food had practically reduced her to a skeleton, and repeated forcible feedings had no effect in changing her convictions. Her persecutory ideas vary in strength from time to time, but the delusions of suspicion from which they spring remain unshaken.

FIGS. 1 AND 2. Appearance during first year at the hospital.
FIGS. 3 AND 4. Appearance during second year at the hospital, after a period of refusal of food due to delusions of poisoning.

The following letters evidently coming from the heart, are characteristic of delusional insanity:

"MARCH 15, 1904.

Dear ——: I am the victim of nerve paralysis, the result of food. I have to eat or I am fed with a tube with nerve-paralyzing food that I choose from the tray. Oh, I think that you and —— were criminals to put me through this. It was an awful thing to do to any human being and I have my opinion of everybody who takes a hand in it. I think it has been a most noble (?) piece of work. I think as the nerves of my body get more benumbed my brain becomes clearer to the outrageous course that has been taken with me. I suppose the next thing, something will be given to put me out of the way altogether. That would be a mercy to this J—— T——."

"TAUNTON LUNATIC HOSPITAL,
July 4, 1904.

DOCTOR STEDMAN: I wish to inform you that I am alive in spite of the deleterious food which has been served to me. Many efforts have been made to poison me in this institution of that I am very sure. I am thin and very hungry all the time. Every nerve is calling for food. Why can't I have help? I ate a pint of ice cream and four oranges Saturday and Sunday. That was all. J——T——.

NORAH KELLEY."

It is worthy of note that, as would be expected in an insanity of the hereditary-degeneration group, the mental deterioration takes in this case the form of delusion rather than dementia.

In this after-history we find, brought into bold relief, the inherent, underlying defect of weak-mindedness which was noted, but only obscurely seen, earlier, for want of opportunity for proper observation, and also the outgrowth therefrom of pronounced intellectual change in the shape of positive delusions. These, together with the other and characteristic manifestations, afford the strongest confirmation of the patient's insanity, intellectual and moral.

The development of a delusional state in the course of moral insanity is, apparently, not uncommon, and affords another and strong argument for the contention that intellectual involvement in some form is an essential feature of the disease, or, in other words, that there is no such thing as a mental disorder affecting the moral sphere alone. Delusions are reported as occurring late in the disease, if at all, suggesting a secondary condition or stage. Comparatively few descriptions of moral insanity include this feature, perhaps because the few cases that reach the hospital for the insane either are not closely observed late in the disorder or, if followed up, have not been recorded, and thus the picture of the entire disease-process as revealed in a certain proportion of cases has been left unfinished. Another and, to our mind, weighty reason is that most of the morally insane are sent to prisons where they rarely come under the observation of alienists. When their insanity has fully and unmistakably developed they are perhaps transferred to institutions for the chronic or criminal insane, where they pass for cases of chronic delusional insanity or dementia. That this view is not overdrawn is plain, even from Lombroso's [6] accounts of the history of a number of prisoners of this class with reference to their intelligence, in some of whom delusions of suspicion and persecution are noted and in others a decided paranoiac tendency is evident. Schüle [7] says of them, "they may develop neuroses, somnambulism, periodical insanity, hypochondria. Dagonet [8] even finds acute delirious mania and hallucinations in the course of the disease. Arnaud [9] concludes a recent and instructive chapter on moral insanity with an account of a typical case with a late manifestation of "delusions of persecution more or less systematized and hypochondriacal ideas." In the opinion of the distinguished and practical psychiatrist, Hack Tuke, [10] "there can be no doubt that in a number of cases of seeming moral insanity there develop *in course of time* definite delusions, especially of suspicion." According to Folsom, [11] "it is the rule that their doubts, imaginations and suspicions deepen into active insane delusions, their mental impairment advances to noticeable dementia, their moral deterioration goes on to such a degree of depravity that everybody wonders why they had not been seen to be insane long ago, and they are secluded in an asylum or elsewhere."

Further research in this direction can hardly fail to enlarge our knowledge of this intricate disorder and its affiliation with paranoia.

The striking parallelism between this and the once famous case of Christiana Edmunds, who was pronounced to be insane by Maudsley and several other distinguished alienists, is sufficient excuse for referring to it here. The extract is taken from an account of the case [12] quoted by Blandford and cited as typical of moral insanity:

"Christiana Edmunds is an example of a person utterly devoid of moral sense or moral feeling in matters relating to herself, though theoretically she doubtless knew that murder was a wrong thing. That she knew perfectly well what she was doing, in purchasing poison and disseminating it broadcast through the town by means of poisoned chocolate creams and that she knew she was therein doing wrong were equally beyond dispute. Her whole conduct before the crime, and her perfectly rational conversation in jail, clearly proved she could have taught a schoolroom of children in the Ten Commandments, and explain to them clearly that it was a wicked act to break any of them, and a most wicked act to break the Sixth Commandment. But no one could have talked with her in jail without being convinced that in her own case she had no real feeling of the wicked nature of her acts, and that she would have poisoned a whole city-full of people without hesitation, compunction, or remorse. Indeed, it may be doubted whether in her later experiments she was really so much influenced by the inadequate motive, which no doubt instigated them at the beginning, as by a morbid pleasure

in poisoning for its own sake, and in the sensation which her secret crimes excited. The terrible story of insanity in her family furnished the real explanation of her state of mind; she had the heritage of the insane temperament."

Dr. Orange, the Superintendent of Broadmoor, under whose care Christiana Edmunds has been ever since her trial, says, "that she has been regarded as of unsound mind by all the medical officers of the asylum who have been here during the last five years. She is at present fairly tranquil, and her conduct is much better than formerly; but I do not regard her as being sane, or fit to be trusted to keep out of mischief. She formerly had periods of depression alternating with periods of subacute mania, but latterly her condition has been more equable."

THE ETIOLOGY AND MODERN METHODS OF TREATMENT OF CHRONIC URETHRITIS.*

BY CHARLES M. WHITNEY, M.D., BOSTON,

Surgeon to the Genito-Urinary Department, Boston Dispensary.

FROM time immemorial the treatment of chronic urethritis, or gleet, has been accompanied with discouragement to the patient and chagrin to the doctor. Over and over again, a patient who has been subjected to dilatation by sounds, to balsams internally, and to the various injections then in vogue, and who is apparently cured, returns again with a profuse purulent discharge which has appeared without any fresh venereal exposure, and demands an explanation from his medical adviser. If this occurs often he becomes dissatisfied with his physician and seeks another, and thus begins his weary pilgrimage from doctor to doctor, and from one quack nostrum to another, until at last the chronic inflammation subsides by itself, or is neglected entirely, and each alcoholic or venereal relapse is dried by capsules of sandal-wood oil, copaiba, or astringent injections.

Phillipe Ricord, whose world-wide reputation and large clinical experience caused him to view rather darkly the future of these patients, used to say to his classes: "Gentlemen, if I am to go to — well, the bad place, I know what my punishment will be: I shall have a lot of fellows with the gleet standing around me, with their lamentations, their importunities, and their prayers to me, to make them well." If such has been, and to some extent is, the future of cases of chronic urethritis, it is necessary for us to study well the conditions which make this possible, and to consider together the means which may be used to avert so unscientific and so unsatisfactory a result.

Chronic urethritis is divided broadly into two classes — the specific or gonorrheal, and simple or non-specific, due to a variety of causes. As from gonorrhea may come not only chronicity of itself, but many other complications which affect the future health of the individual, as well as life itself, it may be interesting to view briefly its history and clinical symptoms.

The early history of gonorrhea is masked in obscurity. Here and there in the writings of the ancients appear doubtful references to an issue or discharge, certain passages in Leviticus suggesting its existence at the time of Moses, certain others its occurrence among the Greeks and Romans; and again, references by Pliny and Galen, by Avicenna and Valescus of Tarentum, show that some local disease was observed. For convenience of description the history of gonorrhea may be divided into three periods: the first extends to 1494, when syphilis made its appearance, the second from this time to 1836, and the third from that date to the present. During the first period up to the fourteenth century the descriptions are vague and uncertain. You will recall that, shortly after Columbus returned from his second voyage to America, a new and hitherto unrecognized disease appeared in the army of Charles the Fifth, who was then besieging Naples, and that it raged with great fury. This, then, was the advent of syphilis which since has spread over the civilized world.

With the attention which this new ailment required, it is not strange that gonorrhea received but scant attention for many years in the current medical writings, but later on, as the nature of syphilis was better understood, there began an increasing discussion in which the medical profession was ranged on diametrically opposite sides. The question which was debated so actively and often so bitterly was whether both of these diseases had a common origin, or were separate and distinct. In short, the medical men up to the time of the eighteenth century were either unalists or dualists, neither side gaining much ground until a misfortune occurred which placed the unalists masters of the situation for the time. One hundred and thirty-six years ago, in May, 1767, on a certain Friday afternoon, the eminent English surgeon, John Hunter, inoculated a portion of gonorrheal pus from a urethra by incision into the glans and prepuce of a patient, — as rumor has it, himself, — and after the usual incubation period, distinct symptoms of constitutional syphilis made their appearance, and victory perched on the banners of those who claimed the two diseases were identical. In the light of our present knowledge we know that Hunter inoculated himself with the pus from a urethral chancre or gonorrheal pus in a syphilitic. But medical progress was by this experiment put back for more than sixty years, until 1836, when Ricord by a careful study of six hundred and thirty-six cases of gonorrhea so conclusively proved the case that no question of identity has recurred up to the present day. But Ricord, brilliant as he was, conversant as his experience made him with this disease, was greatly in error in the light of our present knowledge as to the causation of it. He denied vigorously that it was a specific disease due to a virus, but claimed it was a catarrhal condition brought about by a

* Read before the Middlesex East Section, April, 1903.

variety of causes. From this time up to 1879, little progress was made toward a knowledge of the etiology of this disease. At this time Neisser discovered a diplococcus which was constantly present in gonorrheal pus, and to this he gave the name of the gonococcus. It is to this discovery that the advances which have been made in treatment are due, and to it is due the fact that many acute cases which might otherwise have become chronic have been cured in a few weeks.

Leaving then the history of this disease and approaching the more practical portion of the subject in which you are more interested, I desire to call to your attention a few of the anatomical points concerned, which explain the tendency of the disease to assume a chronic course.

The urethra in the male is about eight inches in length and is divided into three parts, the penile or spongy, occupying about six inches, dilated at its internal end into the bulbous portion, the membranous, about one-half an inch, and the prostatic, one and a quarter inches. The shape varies in each portion, the meatus being a vertical slit, and directly behind this is a dilatation, the fossa navicularis, narrowing again until we approach the bulb, where we have again a dilatation amounting to almost a pocket, and this again followed by a sharp constriction in the membranous portion. The prostatic urethra again enlarges, and we have, therefore, throughout the whole urethra alternate dilatations and contractions. This, then, is one element which physiologically prevents the free drainage or flushing out of gonorrheal pus or other secretions.

As accessories to the urethra we have various glandular structures which often become infected. In the central portion are the glands of Littre, compound racemose glands and follicles, and in the fossa navicularis one large one on the upper surface about an inch from the meatus called the lacuna magna. Opening into the bulbous portion are the two ducts of Cowper's glands. The glands themselves are between the folds of the triangular ligament in the compressor urethræ muscle, and the ducts are from an inch to an inch and a half in length.

In the prostatic portion we have, in the middle line, the veru montanum, and on each side are the prostatic sinuses, and in these are the orifices of the prostatic glands. Nearly at the top of the veru montanum is the utriculus masculinum, and in this are the openings of the ejaculatory ducts. Contained in the folds of the triangular ligament is the compressor urethræ or cut-off muscle, the great anatomical dividing line between the anterior and posterior urethra. Connected also by the ejaculatory ducts are the seminal vesicles.

From this necessarily brief résumé of the essential points in the anatomy of this region we see at once that we have in these various glands avenues through which infection may pass to other accessory organs or in which the gonococci may remain for indefinite intervals, unaffected by antiseptic or astringent injections, an ever present menace to the health and comfort of the individual.

In acute gonorrheal urethritis, the pus containing the specific poison having been deposited at or within the meatus, there is an interval of from three to five days before symptoms begin to appear. At the end of this time a sensation of itching occurs at the meatus, a moderate degree of scalding during urination, soon followed by a purulent discharge. If this discharge be examined early the gonococci will often be found outside the pus cell, but soon become intra-cellular as the discharge increases. The gonococci penetrate very rapidly through the epithelial layers of the urethra, entering even the submucous tissues. By a process of phagocytosis the leucocytes seize upon the gonococci and a free discharge of pus results, removing many from the passage. At the same time a desquamation of the superficial epithelial cells occurs, and these, with the extra-cellular diplococci, are expelled with the flow of pus. In this manner the inflammation rapidly spreads along the anterior urethra, involving on its way the glands and follicles until it reaches the compressor urethræ muscle, and here it meets its first anatomical barrier, and if, as is sometimes the case, it does not progress beyond it, it remains an anterior urethritis. In the majority of cases, however, it does so progress and involves successively the membranous and prostatic urethra and produces the various complications so well known to you, — prostatitis, cystitis, seminal vesiculitis and epididymitis. As the disease continues the discharge increases, rapidly at first, and then slowly subsides, becoming less purulent and more mucous until it is a purely mucous secretion similar to a catarrhal discharge in any other region, and it is this form which most commonly persists and forms the chronic urethritis with which this paper deals especially. Examined microscopically at this time the discharge is found to consist of mucus, more or less fibrin, leucocytes, and perhaps an occasional intra-cellular organism.

The exact time at which a subacute urethritis becomes a chronic one is not easy to define in precise terms, for much depends upon the treatment adopted at the onset and upon the question of a primary infection. It is perfectly obvious that a urethra narrowed by strictures or abnormal from repeated attacks of gonorrhea does not heal as rapidly as one which was normal at the onset of the disease.

Assuming, however, that the average duration of properly treated cases of gonorrhea is about six weeks, exclusive of the modern methods of treatment by irrigations of permanganate of potash or the silver salts which are still, many of them, unavailable in the ordinary case as treated in private practice, we may say that a chronic case is one in which there is still a persistence of a mucous or muco-purulent discharge at the expiration of ten to twelve weeks.

So far we have discussed only specific urethritis, but we also have the non-specific forms which are

more common than is often stated. These are produced by a variety of causes, chief among them being uric acid excess, febrile attacks, trauma, syphilitis, tuberculosis and alcoholic excesses, with also a probable form of bacterial infection by other organisms than the gonococci. In this form the secretion contains no gonococci, the symptoms are less acute, the complications are fewer and the discharge is less purulent, often being simply mucous or watery. The reaction to treatment is not at all satisfactory, and the tendency is to assume a chronic course which persists until the cause, often constitutional, is removed.

Assuming, then, that a patient presents himself for treatment with a history of urethral discharge from one to two years' duration, what should we do in the light of modern science to ascertain the source of this discharge, and having ascertained this important fact, what treatment should we adopt to cure it?

To insure uniformity and thoroughness in the examination and as a result of several years' clinical work in this special line I have compiled a record blank which incorporates most of the

Diagnosis, ...
Treatment:

essential points. Having heard the history, the patient should remove sufficient clothing to allow free access to the genitals, and these should be carefully inspected. The general size of the penis, with reference to the probable urethral calibre, the length or absence of the prepuce, any abnormality of the testes, epididymes, cords, or groins should be noted. If discharge is present, the meatus should be wiped off with a moist piece of gauze and with a sterile platinum wire a small portion of this secretion should be transferred to a slide and examined microscopically. The presence or absence of gonorrheal organisms is of the greatest consequence in determining our treatment, as well as the relative proportion of leucocytes, mucus, fibrin or epithelium.

While this examination gives us much valuable information concerning the character of the discharge it does not aid us materially in determining its source, and it is for this purpose that our next steps are taken. It was formerly a routine procedure to ask the patient to urinate into two glasses and by comparison of these to form some idea as to whether the anterior or posterior urethra was chiefly affected. Useful as this is in acute cases where there is a profuse discharge, it is utterly valueless in chronic cases with scant discharge, for there is not enough in the posterior urethra to flow back into the bladder, but it remains in the urethra and is washed out by the first stream of urine. Therefore, the first glass contains all the material from the whole urethra. A more accurate method is to thoroughly wash out the anterior urethra with 4% boric acid solution. This fluid containing the discharge anterior to the compressor urethræ muscle, is saved for comparison.

The patient should now urinate in two glasses. If both portions are clear we may conclude that the source of the discharge is in the anterior urethra. If the first contains shreds and the second none it points to the posterior urethra, while if both are cloudy or contain many shreds, it indicates that there is an inflammation of the bladder itself or considerable discharge from the prostatic urethra flowing back into it. If the bladder is empty it should be filled with boric acid solution and the prostate and seminal vesicles massaged; the urine or solution will then contain the material from these sources. This four-glass test gives us, then, a fairly accurate idea of the source of the greater part of the chronic discharge.

Having made this routine examination and having washed out from the urethra the various pathological elements, of what do we find them to consist? Where the discharge is fairly profuse we have a turbidity of the urine which does not clear upon adding acetic acid, which differentiates it from phosphaturia, a not uncommon condition in chronic urethritis. Where the discharge is scanty it appears in our glasses in the form of floating particles varying in size and consistency, and to these has been given the name "clap shreds." From the shape of these, little is to be learned, although it has been the custom to assume that those of a hook or comma shape had their origin in the prostatic urethra.

Microscopically these shreds are found to con-

sist of mucus, fibrin, epithelium, pus, or of combinations of all these. Without the microscope we receive some aid in determining these facts by the behavior of the shreds in the freshly passed urine, the heaviest which sink quickly are chiefly composed of pus, and the lightest, which float for some time, are mucus. The epithelial shreds occupy an intermediate position in this respect. Beside the symptom of discharge, which is constantly apparent to the patient, we have other and graver symptoms in these chronic urethral catarrhs to which only a passing allusion can be made. When the inflammation invades the prostatic portion we have many and serious disturbances of the sexual functions. These are due to extension to the prostate and result in a lessened sexual desire, deficient erection, premature ejaculation and often nocturnal emissions. With these we are apt to have various neurasthenic symptoms and radiating pains in various directions. Relapses occur again and again, especially in this region, giving rise to symptoms of cystitis of the neck of the bladder, frequent and painful micturition, with often the appearance of considerable blood at the end of urination. These attacks subside under sandal-wood oil and diuretics only to recur again and again until vigorous and continuous local treatment has been instituted for their relief.

Of what then does our treatment of these stubborn urethral cases consist?

The theory of treating a chronic urethritis is beautifully simple, and consists in destroying and removing the gonococci and curing the resulting catarrhal inflammation. But when we remember the organisms are often situated in the submucous tissues and in the remote recesses of branching or racemose glands, and that the resulting inflammation is of a plastic nature which interferes with the normal resiliency and circulation of the urethra, we see why it is that gleet, not properly and thoroughly treated, pursues so stubborn and intractable a course. The chief advances which have been made by modern medicine in this direction have been, first, in giving us practical antiseptics which destroy the organisms without injuring the tissues and, second, in providing us with instruments by which we may remove the products of plastic exudation, and, third, in showing the importance of direct local treatment applied to the prostate and seminal vesicles.

To destroy the gonococci we have the choice of several silver salts, the latest of which is argyrol which contains 30% of silver vitteline. protargol, about 8-10% and permanganate of potassium. If the discharge contains gonococci, before proceeding further we should attempt to destroy them. For this purpose we may use 10% argyrol solution to be held in the urethra for five minutes each day, applied by the physician, and a 4% solution to be used by the patient three times a day to be held five minutes each sitting. We may use practically the same strength of protargol. At the present time argyrol seems more satisfactory, as it is practically non-irritating in any strength and contains the largest percentage of the silver salt. We may use irrigation of permanganate of potash by the gravity method brought into popularity by Janet and Valentine, by which the whole urethral tract is flushed out without the use of a catheter, the force of gravity obtained by elevating the solution about six to nine feet being used to overcome the cut-off muscle. By a little practice this is quite easy to do and greatly aids us in treatment. The patient should lie on a table and the anterior urethra should first be thoroughly irrigated. The tip is then pressed firmly into the meatus and the solution gradually allowed to overcome the resistance of the compressor urethræ and to fill the bladder. In some cases this is quite difficult to do at first, but by having the patient attempt to urinate or by instructing him to breath deeply, the fluid soon enters the bladder. It is superior to irrigation with a catheter because in acute cases no foreign body is introduced into the urethra, and in both acute or chronic cases full dilatation is obtained which effectually washes out all inflammatory products.

IRRIGATOR.

Messrs. Leach & Green have constructed for me an irrigating stand which does not require fastening to the wall, but may be placed where-

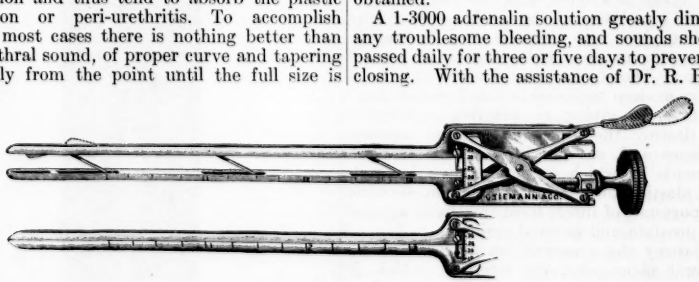
ever it is needed. A glass receptacle containing 2,000 cc. is raised by a pulley to the height required, the maximum being seven and a half feet, which gives sufficient force for almost any case. In hospital and private work I have found this very convenient and useful. Where this method cannot be carried out for various reasons, we obtain good results by ordering one grain tablets of the permanganate of potash to be dissolved in a half tumblerful of hot water, making a solution of about 1-2000 to be used for home treatment. These treatments at home only relieve the parts which the injection reaches and rarely penetrate to the deep urethra. Having by these various means lessened the discharge, or at least made it free from gonorrheal organisms, we are now prepared to examine the urethra for localized areas of inflammation. For this purpose the patient first urinates, and then with the largest bougie-a-boule which the meatus will admit, the urethra should be examined and careful record made of any tender spots for later endoscopic treatment. Should a stricture be present which will not admit a full-sized bougie the next smaller should be selected until we find one which will pass. If 10 Fr. will not pass it is useless to try further, but a soft bougie should be used. Note should be made of any bleeding following these manipulations and of the location, calibre, sensitiveness and character of all strictures.

Whether or not any stricture is found and whatever the cause of the chronic discharge, ruling out of course the sources too far away from the urethra to be affected by it, the cardinal point in treatment is the thorough dilatation of the urethra from the fossa navicularis to the prostate. The object of this is two-fold, to remove from the follicles their contents, and by pressure upon the urethral walls to stimulate circulation and thus tend to absorb the plastic exudation or peri-urethritis. To accomplish this in most cases there is nothing better than the urethral sound, of proper curve and tapering gradually from the point until the full size is reached. As the average urethra is about 30 Fr. and the meatus 24 Fr. it is often impossible to pass a sound of sufficient size to dilate the deeper portion without cutting the meatus. Where this is undesirable we may use the Kollmann dilator which is invaluable in cases of gleet where no stricture is present. This consists of four blades which are opened by turning a screw in the handle which registers upon a dial the size reached. The part of the instrument which remains in the meatus is about 22 Fr., and is not affected by the dilatation of the blades which open lower down. The instrument is covered by rubber which protects the urethra. It produces far greater dilatation than can be obtained in any other way as it is quite possible to dilate the prostatic portion to 35 or 40 Fr. without marked discomfort to the patient and with great improvement in the local condition.

In the treatment of stricture it is not the equal of the older method by the sound, for between the blades are spaces where the pressure is not as firm, and we do not get, therefore, a uniform dilatation. With the use of any instrument, however, we not infrequently find at the outset a tight meatus, and before further treatment can be instituted, this must be cut. Before cutting a meatus indiscriminately its physiological use should be borne in mind. Normally of smaller size than the urethra it regulates the size of the urinary stream. If too large an opening is made this function is destroyed and great discomfort to the patient results, for the urine cannot be expelled with sufficient force to direct it away from the clothing. Beside this an atrophy of the normal urethral glands takes place in the navicular fossa. We should therefore use care in dividing the meatus to maintain as far as possible its relative size.

A simple method of doing meatomy is to first thoroughly cocainize with 10% solution using a small cotton swab which is placed in the meatus and allowed to remain while the instruments are being prepared. A small, blunt-pointed tenotome is best for this purpose, and the incision should always be made on the floor of the urethra. After incising to the size we think right, it should be measured by the bougie-a-boule, and if it is not large enough the knife should be reinserted and the cut enlarged until the proper calibre is obtained.

A 1-3000 adrenalin solution greatly diminishes any troublesome bleeding, and sounds should be passed daily for three or five days to prevent rapid closing. With the assistance of Dr. R. B. Rees, I have recently devised a new meatome for this purpose and also for cutting strictures in the penile urethra.



MEATOME.

The accompanying cut illustrating the instrument is three-fourths actual size, and shows all the details so clearly that a lengthy description of the different parts seems unnecessary; the motion of the blades is perfectly parallel, and dilatation is easily and accurately accomplished by means of the thumb-screw at the end of the

handle propelling a rod dovetailed in the lower branch; the brackets which are jointed to this moving rod cause the blades to separate, the extent of dilatation is indicated in the metric gauge on the scale appearing on both sides of the instrument, the scale is fastened to the lower branch, the indicator to the upper one. The concealed knife may be withdrawn after dilatation to any desired distance by means of the small handle extending beyond the instrument. The shaft of the instrument is graduated in inches commencing at the point where the knife appears from its concealed position. Cross-bars adjusted to both sides of the handle stiffen the instrument so that it is rigid from end to end at any degree of dilatation. As a stricture is cut upon the upper surface of the urethra, and the meatus upon the floor, the scales are reversed for ease in reading in the two positions.

The instrument has been beautifully made by Tiemann & Co., to whom I am indebted for valuable suggestions. In using the urethratome it should be introduced into the urethra, the desired degree of dilatation obtained and the stricture or meatus quickly divided by withdrawing the small buried knife. By this means a uniform result is quickly obtained and a single clean incision, which is a great advantage over the several " nicking " cuts unavoidable by any other accurate method.

After dividing the meatus when necessary we should dilate the urethra once or twice a week and irrigate the anterior and posterior urethra with 1-3000 permanganate of potassium or 1-4000 silver nitrate solution in order to flush out material expressed from the follicles, using the gravity method. One can use a large hand syringe with a special rubber tip and a nipple shield to prevent the fluid escaping into the face of the operator. An addition to our appliances for this purpose is the irrigator tip devised by Dr. R. B. Rees, which consists of a glass Pg. 19 shield which perfectly protects the operator while irrigating these gonorrheal patients.

Having assured ourself of the thorough dilatation of the urethra we should next examine the prostate and vesicles and massage them, saving the secretion for microscopical examination, and after the massage irrigating the bladder and urethra as after dilatation. To properly apply this massage the patient should lean forward resting the hands on a stool, and with the index finger the prostate and vesicles should be gently stroked toward the median line. These sittings should last from three to five minutes, and should be repeated once or twice weekly, and always with the bladder filled with urine or boracic solution. After massage the fluid containing the expressed material has an opalescent appearance. When the prostate is chiefly involved one of the most valuable aids to treatment which we have is the deep instillation of nitrate of silver solutions of varying strengths, beginning with five grains to the ounce and increasing to ten or fifteen grains. With an Ultzmann syringe lubricated with glycerine a few drops are placed just behind the compressor muscle and this applies itself to the whole prostatic urethra. The patient experiences an intense desire to urinate which continues for an hour or two.

Occasionally a few drops of blood follow but this is of no especial significance.

To treat localized erosions we may avail ourselves of the urethroscope, and the best instrument for the purpose is an electrical one made by the Rochester Electro-Surgical Company. The urethral mucous membrane is inspected while the tube is being withdrawn, and any localized area of inflammation touched with a strong solution of nitrate of silver. This method is of most value in the cases which have resisted other forms of treatment and in which the only symptom present may be a slight sticking together of the lips of the meatus. Where there is an atonic condition of the urethral lining the psychrophor of Winternitz, may be used. This is a hollow sound into which a current of alternating very hot and cold water may be introduced, which is often followed by benefit. The patient may use with advantage during these treatments various solutions by a syringe, some of the best being permanganate of zinc in the strength of 1½ gr. to the ounce, sulpho carbolate of zinc, 2 to 5 gr. to the ounce, and permanganate of potash as already mentioned, as well as many other astringents in the formulæ familiar to us all. When the discharge is profuse internal medication should be used and the oil of sandal wood is most satisfactory in its action. As this oil varies very widely in quality, only the purest should be prescribed. Intervals in the treatment should be observed in order to avoid over treatment and keeping up a mechanical irritation which tends to prolong a catarrhal condition.

Confronting us always in these cases is the vital question, When is a patient well, and no longer capable of infecting any one else? Briefly, when there is no longer a discharge, when the shreds contain neither pus, gonococci or a large amount of epithelium, and when, furthermore, after producing a discharge by nitrate of silver or corrosive solution no organisms are present. Also, when after alcoholic or sexual excesses no discharge appears we may be reasonably sure that the patient is well.

In conclusion I desire to say again that while we have in chronic gonorrheal urethritis a most stubborn, intractable and sometimes incurable ailment, still, these methods of treatment which I have described to you seem to me to be progressing in the right direction, and to give hopeful promise of future benefit.

When in gonorrhea we have a disease which is responsible for 75% of the blindness of the world and for one eighth of all the pelvic ailments of women, and when from consequences near and remote a person may be a permanent cripple in one or many joints, may be impotent, or may finally die from kidney disease following stricture, it seems reasonable that such a disease in its acute or chronic manifestations is worthy of the most careful study of every thoughtful physician.

Clinical Department.

MASSACHUSETTS GENERAL HOSPITAL.

CLINICAL MEETING OF THE STAFF, TREADWELL LIBRARY, FRIDAY EVENING, APRIL 15, 1904.

DR. F. B. HARRINGTON in the chair.

ULCERATION OF PRIMARY BRONCHUS; PERFORATION INTO PULMONARY ARTERY.

BY W. W. GANNETT, M.D.

The case of which I am about to speak is one of ulceration of the primary bronchus with perforation into the pulmonary artery. This man was a sailor, thirty-seven years of age, and single. Had been sailor in early life and after that a painter. There was a history of gonorrhea, but no syphilis. For three years previous to entering the hospital he had had a continuous cough, but no expectoration. Two days before coming into the hospital he had expectorated a large amount of blood, a quart or more. From that time the expectoration was very much like that of a case of tuberculosis. On the second day of his entrance, about eight o'clock A.M., he suddenly coughed up about a quart of blood, and immediately became unconscious. Saline solution was immediately administered. From eight o'clock in the morning until the next evening he coughed no blood. Twenty-four hours after this a large amount of blood gushed out, and he fell dead.

The interesting point in this case was the extensive hemorrhage at first, and the long interval between that and the next one. During life the origin of the hemorrhage was very doubtful. In some respects it resembled an ordinary tuberculosis, but it was very unique. It was not like death from aneurism, because in this the hemorrhage is usually continuous until the death of the individual.

Post-mortem: There is very marked thinning of the wall of one of the primary bronchi, while at one point there can be seen a very distinct opening in the bronchus, connecting with the pulmonary artery. We thought at the time this might be the results of tuberculosis or of syphilis. There was evidence of syphilis in the testes and slight cicatrix on the tongue which suggested a syphilitic lesion.

We can easily see how the hemorrhage occurred. The bronchial wall being exceedingly thin, the efforts at coughing caused a breaking of the thin wall of ulceration. He then went for three days without hemorrhage, bleeding very little during the first twenty-four hours of stay in the hospital. The interval gave an opportunity for a thrombus to form. It seems to me that when the second hemorrhage occurred, the thrombus which had formed was dislodged, and the blood came out with a gush.

A CASE OF INTUSSUSCEPTION. INTERSTITIAL COLITIS, SIMULATING CANCER OF THE RECTUM.

BY J. W. ELLIOTT, M.D.

CASE I. This patient does not speak a word of English, so the history is very unreliable. We could not make a diagnosis at first. He was perfectly well up to a few weeks ago, and when he entered the hospital his bowels were moving every day. He began then to have ten or twelve movements a day. There was pain, but not radiating. At times the pain stopped. He vomited constantly during this period, retained very little food, but lost very little weight. He was feeling wretched, and looked as though he would not stand an operation. Later the diarrhea ceased and there was considerable distension. We were able to give him a good movement at one time, then the next time could not. The most noticeable thing about him was a hard tumor just above the umbilicus, with coils of contracting intestine visible all about. At first everybody thought it was obstruction due to cancer. At the time of the operation, just before I made the incision, this lump was very much larger and down to one side. At the operation, this hard lump proved to be the whole length of the descending colon, and very much swollen, as large as my wrist. I did not feel sure of the diagnosis until I opened the colon, and out popped the invagination. Of course, the intestine was gangrenous and swollen, and there was nothing to do but to amputate it. My plan was to make an artificial anus just above the transverse colon, but when I pulled up the transverse colon, I found it would produce so much tension that it seemed unsafe, so I finally pulled the whole thing out. The opening was enormous. I put a Mixter tube in the transverse colon and stitched the gaping end into the wound. He was in poor condition, and his abdominal wound was closed with through and through stitches, which was all right, but the Mixter tube would not stay in more than a few days. There was soon a fecal fistula opening into the wound with the intestines bulging out. By stitching that together and to the colon above, we finally got a good result. The mortality is something like 90% in these cases, so I think we were very fortunate. The Mixter tube was very disappointing to me. It is supposed to carry the feces away, but it does not do it.

CASE II. This case had constipation and dyspepsia for the last twelve years, but last few months had a subacute difficulty, constipation and diarrhea alternating. She came in for a tumor of the rectum. There was a hard mass there that felt like a cancer. Pus and blood were coming constantly, and I had no doubt it was cancer. I intended to resect the rectum and part of the sigmoid flexure, but when I opened the abdomen I found the whole gut, from the anus up to the splenic flexure, was one solid tube of large calibre, and so fixed that I could hardly move it. Resecting was out of the question, so I simply made an artificial anus on the other side. The mass had such a strange appearance when we came to look at it that I doubted whether it was cancer after all. We had it scraped and examined, and the report came back negative — simple inflammatory tissue. The whole descending colon down to the rectum was chronically inflamed, — interstitial colitis.

I submit that this is the proper treatment for such an inflamed condition of the lower bowel. Sidetrack the feces, and wash through. The patient is now very much better. There has been no sloughing, and the pain is all gone. Of course, everybody does this operation for tuberculosis of the rectum, but I do not know of its being done for a chronic inflammatory condition of the bowel.

A CASE OF CHRONIC LEUKEMIA. A CASE OF SUBACUTE ARTICULAR RHEUMATISM. A CASE OF METHEMOGLOBINEMIA. A CASE OF EMPHYSEMA. CHRONIC PLETHORA. AN UNUSUAL CASE OF SCLERODERMA.

BY E. G. CUTLER, M.D.

CASE I. The first case I wish to show is a case of chronic leukemia. The patient felt well until March

29, then noticed lumps coming in the neck. Lost in weight, color and strength. Hemoglobin 50%, whites 711,900, reds 3,020,000. Differential count of 500 white blood corpuscles showed 500 lymphocytes. April 1 whites numbered 712,000. On April 9 reds were 2,400,000, whites 592,600. The glands in the neck can still be felt, but are by no means as large as when first came in. Glands enlarged under the arms. The abdomen was considerably distended and glands were felt, which seem to be behind the intestines. The spleen is somewhat enlarged. This all answers the description which one sees of lymphatic leukemia. Dr. Cabot suggested that we try the x-rays on him.

CASE II. A case of subacute articular rheumatism with subcutaneous nodules. They are composed of fibrous tissue, and usually grow from the size of small shot up to the size of a pea. They are said to occur in other diseases besides rheumatism. The books all say these come about the joints, but I have seen four cases where they came on the forehead. Microscopically they are seen to be composed of round and spindle-shaped cells.

CASE III. She has had severe headaches coming on in paroxysms for three or four years and has been given headache medicines. When she came in here her lips were very blue. We tested the blood and found that instead of having either blue or red blood, that she had brown blood. Spectroscopic examination shows bands characteristic of methemoglobin.

CASE IV. A case of emphysema, with tremendous cyanosis. He has a red blood count of 8,432,000. He had severe headaches, which medicine did not seem to help at all. We bled him about a pint, and he has been better ever since.

CASE V. I have two other cases of chronic plethora in which there is polycythemia as well. One is eighteen years old, and is here for the first time. You will notice the red face. There has been some retinal hemorrhage. Reds 8,120,000. Hemoglobin 80%. Whites 10,000. She was bled on March 10, when she showed an increase of reds. After bleeding there was a decrease of reds to 5,000,000. On the 19th they were 3,000,000, rising later to 4,040,000. She is more comfortable than she had been. Very soon after this we bled again, and the count went down to 3,608,000. She is not so dizzy and has no headache now. She looks a great deal better, although the color is still very high. Blood pressure is 130. (Riva-Rocci, — narrow cuff.)

CASE VI. The next patient has been here twice before for plethora. She is so full of blood that there is pigmentation in the hands. Those parts of the body which are exposed soon became pigmented. At first the reds were 8,844,600. Hemoglobin 20%. About a month later the count was over 9,000,000, then went down to 8,426,000, and up again to over 9,000,000. We then bled her and it came down to 8,872,000, and a week afterwards lower still. But the headaches returned and the reds again went up to 9,000,000, when we bled her once more and they came down. She thinks there is no question but that the bleeding was beneficial to her.

CASE VII. A progressive generalized scleroderma marked by hypertrophy and atrophy of the cutaneous pigment and atrophic condition of the skin. There is immobility of the joints, etc. In Dr. White's opinion, it is a condition of the cutaneous tissues quite different from anything of the ordinary type. The disease has been coming on for a considerable time. Three and a half years ago she became blue, and gradually the skin became dark.

FOUR CASES OF FINNEY'S OPERATION ON THE STOMACH.

BY JAMES G. MUMFORD, M.D.

I have to report four cases of gastro-duodenostomy, performed by Dr. Finney's method, which, members are aware, is designed to give a very large, free opening for stomach drainage into the duodenum in cases of pyloric stenosis, — cases which are not malignant and in which active ulcerations are not present. These four cases are all dissimilar and, as the results are good, they give us further light on the possibilities of this operation which, I am coming to believe, with Dr. Finney, is capable of extensive application, is extremely useful in suitable conditions, is attended with a low mortality, and is not especially difficult of performance.

CASE I. The first case, Mrs. McG., is reported three and a half months after operation. I referred to the patient briefly at our February meeting. She is a married woman, forty-six years old, who was sent to me at the hospital in December last by Dr. Frederic Winslow.

She has a history of many years of dyspepsia. About one year ago she began to have pain in the epigastrium, coming on about fifteen minutes after eating. The pain lasted two or three hours, unless relieved by vomiting. For ten weeks she had vomiting almost daily, and for three weeks had been nourished by enemata. She had lost about twenty pounds and was greatly emaciated. The symptoms were unrelieved by lavage or other palliative treatment. Analysis of the gastric contents showed much undigested food and free HCl.; the stomach was but slightly dilated.

I performed Finney's operation on January 1 last. There were numerous adhesions found about the pylorus, which was fixed high and sharply kinked. The patient had an uneventful convalescence; solid food was taken on the sixth day and she was about on foot at the end of three weeks. She is now free from pain, has an excellent appetite and, as she herself tells you, feels perfectly well.

CASE II. Shown two months after operation.

Dora S. Patient of Dr. J. M. Jackson, age forty-five, nine children. Has had dyspepsia for many years. Her chief symptoms were pain in the epigastrium after all food, with increasing vomiting since last August. She was temporarily relieved by treatment, but without lavage uncontrollable vomiting persisted. She had pain after eating. At the time of her entering the hospital, Feb. 20, she was vomiting practically all food, and was alarmingly weak and emaciated.

Gastric contents: Undigested food, absence of HCl.

Operation Feb. 23. The stomach was found slightly dilated, with adhesions about the pylorus, the lumen of which was much thickened, admitting the tip of the little finger only. There were three scars on the anterior aspect of the stomach. The patient rallied well with little vomiting, and on the sixth day was eating solid food with care.

The convalescence has been rather slow, but the symptoms have steadily improved, and the nurses now report that the patient has an enormous appetite and an unimpaired digestion.

CASE III. Shown three weeks after operation.

She is of a type quite different from the first two. A young girl in fair condition, but with an enormously dilated stomach.

Emma L. H. Eighteen years old; was a patient of Dr. J. M. Jackson, who had observed her for several

years. She is a vigorous, well-grown girl. About five years ago she began to have nausea and distress after food. This was relieved occasionally by vomiting. She never noticed old food in the vomitus. She had much careful treatment, which relieved her for the time, but her symptoms would recur. The stomach gradually became dilated, reaching nearly to the pubes; though after several weeks of treatment it descended only two inches below the umbilicus. There was no ptosis. Operation was advised on the principle of an operation for chronic appendicitis, — to avoid future trouble.

On March 25 the abdomen was opened; a thin-walled, dilated stomach was discovered, with a high pylorus, adherent and slightly kinked. An extensive Finney operation was done. The convalescence has been absolutely uninterrupted. Within a week the patient ate solid food and now indulges a vigorous appetite, without subsequent discomfort. By percussion, we now show the lower margin of the stomach to be two inches above the umbilicus.

CASE IV. Shown ten days after operation.

Mrs. S. Age, forty-four; a patient of Dr. C. E. Williams, of Roxbury, was much the most difficult and interesting of these four cases. She had had gastric symptoms for nearly ten years, — symptoms characterized by distress after taking food. For about one year she had severe cramp-like pains in the epigastrium immediately after all food; was constantly hungry, but her pain was increased by food; she had much nausea but no vomiting. Had lost fifteen pounds, was always thirsty, but water distressed her, and she was in a miserable, emaciated condition.

The patient was brought to me six weeks ago. Physical examination showed the pelvic organs to be not abnormal, the abdomen boat-shaped, retracted and tender in the epigastrium. Somewhat distended below the navel, with a movable right kidney, easily palpable. By percussion it was estimated that the stomach was prolapsed, the lesser curvature being about two inches above the navel. It contained forty ounces; at first there was absence of HCl., but under treatment acid was found later. Careful dieting, lavage, HCl. and salts gave relief for a short time, but the symptoms returned and the patient grew despondent.

She was sent to the hospital, where I opened the abdomen on April 5. The stomach was found prolapsed, but an interesting point was an hour-glass constriction in that organ about four inches from the pylorus. The cardia was thin, pale, distended. The pyloric extremity was thick and injected. There was very little pyloric obstruction. There was a single stone in a flabby, empty gall bladder, which was non-adherent and showed no evidence of inflammation. The hour-glass stomach was treated by an extension of the Finney principle, — so far as I know, the first time this principle has been applied to hour-glass stomach. By this method very free drainage was established.

The stone was removed from the gall bladder and cholecystostomy established through a stab wound on the right. The patient has done well, and is now eating solid food without discomfort.

There are a few points in connection with Finney's operation which are interesting, and after my limited experience with four cases, I am encouraged to believe that this procedure is to prove a very valuable addition to our resources.

The drainage established is very free; the route of drainage does not depart from the normal course.

The convalescence is very comfortable; far less stormy than after gastro-enterostomy; very little vomiting, nausea or pain.

In the last case I hope we have demonstrated that the symptoms of ptosis of the stomach may sometimes be relieved or cured by this operation. Certainly we have shown that in hour-glass stomach it is applicable, if not ideal.[1]

REMARKS ON THE RESUME OF DR. F. B. HARRINGTON'S SERVICE FOR THE YEAR 1902.

BY E. A. CODMAN, M.D.

This is the third report[2] of this kind which has been shown at these meetings, representing a total number of 667 cases, the results of which have been traced. I want to say a few words about the advantages which might be obtained by having similar reports made of the services of each surgeon. In the first place, it is a very valuable training for the individual who examines the cases and makes out the report. I think that I have gained as much valuable surgical experience in making out these reports of Dr. Harrington's service as I have gained in the actual operating on a portion of these cases, so that I feel more than repaid for the little work which such a system requires. No matter how favorable impressions of certain operations may be, when a careful examination of the patient is made a year later, many disagreeable symptoms may often be found. A knowledge of these symptoms does a great deal to help in future operations in similar cases.

We all must acknowledge that good surgical judgment is obtained rather by personal experience than by the examination of statistics; but in looking up the after results of one's cases, we are not dealing with statistics, but merely adding to our personal experience in a way in which we would not do unless we made a special point of it.

The advantages of such a review of the cases to Dr. Harrington is also apparent. I have written to these cases to return during the first two weeks of Dr. Harrington's service of the following year, so that if any case presents itself which shows an interesting or instructive result, I could call Dr. Harrington's attention to it, and in a very few minutes in the morning he has been able to run over the cases which present themselves, thus his personal experience is also enlarged in a most instructive way.

As these reports accumulate year after year, the figures add up surprisingly, so that in case Dr. Harrington wishes to look up any one of the classes of cases in these tables, he may turn to these leaflets and get a good bird's-eye view of the results. Perhaps he may wish to compare his results with the report of some operator whose paper he is reading. For instance, in the past three years in Dr. Harrington's service, there have been 42 hernias, 14 fibroids and 127 cases of appendicitis. By turning to the remarks on

[1] Since reporting the above four cases I have had one other quite similar in symptoms and physical condition to Case 2. It is at this writing four days since the operation; the patient is eating soft food freely and in spite of a cardiac lesion, promises to make a speedy convalescence.

[2] Report published in JOURNAL, June 9, 1904.

the cases, Dr. Harrington could find what the result of about one half of these cases has been a year after the operation. It enables him, too, to reflect on what cases are in general unsatisfactory; for instance, in the gynecological cases in which the cases have been distinctly less favorable than any other class. In order to improve results, it is first necessary to know whether they are bad or not, and the account of the gynecological cases given at discharge in the annual report would be very much more favorable than the account by the patient a year later. Then as to the value of these reports in general, to those of you who take the trouble to read them. I think from these reports the general practitioner can obtain a fairer idea of the results of the hospital cases than he can from the papers which are written by individual surgeons in classes of cases in which they are more interested, and naturally have taken more pains than on the general run of cases.

If I should put the statements in this report as questions, I doubt if many of this audience would be able to give very satisfactory answers of what the results were. For instance, of the results of the thirty-one interval cases of appendicitis which have been reported in these three years, How many had received no improvement from the operation? The answer is, four. Of the eighteen cases of cancer of the breast, How many show recurrence at the end of a year? The answer is five, although two were not positively cases of recurrence.

The report is also valuable as showing the variety and general character of the class of cases which the surgeon is called upon to treat, and as representing one ninth of the hospital work. When we consider that we have in these three reports 667 after results, and that this number might have been multiplied by 9 if the assistant surgeon in each service had made a similar report, the aggregate number of 6,003 might be of *some* value statistically, although not of great value, as the classification of the results would have to depend on the judgment of the individual who looked them up and marked them as, "perfect," "good," and "no improvement," etc.

If some arrangement could be made by which the house officers should see these late results, it would be very instructive for them, for I feel sure the house officer in graduating from this institution gets a very much more favorable idea of the results of surgical operations than he is really justified in having.

VULVO-VAGINITIS IN CHILDREN. A METHOD FOR OBTAINING SPUTA FOR BACTERIOLOGICAL EXAMINATION IN INFANTS AND YOUNG CHILDREN. MOUTH TEMPERATURE AND RECTAL TEMPERATURE.

BY L. W. TOWNSEND, M.D.

Unfortunately, vulvo-vaginitis is a very common disease in all children's clinics, and of serious import, owing to the presence in nearly all the cases of the gonococcus. The treatment is often difficult and generally unsatisfactory. I have used lately, however, in the children's clinic a 4% solution of argyrol injected slowly through a small catheter into the vagina, to the extent of one ounce, and held there for ten minutes, the child lying on her back. In several cases the improvement was very prompt, and there was little or no discomfort to the child, as is the case with larger douches of boric acid or corrosive sublimate.

A child under five or six years of age coughs up sputa into its mouth, but swallows instead of spitting it out. Hence the diagnosis of many cases is often difficult. Especially is this the case with cases of delayed resolution in bronchopneumonia, many of these having an evening rise of temperature, so that the tuberculin test cannot be used.

Holt has recommended the passage of a stomach tube and the examination of the mucus that adheres to it; others have used emetics and examined the vomited mucus.

A method recently described by Findlay, and used for some time in the French hospitals, I have found very simple and very satisfactory. It consists in sweeping the finger covered with gauze over the glottis and epiglottis. This causes reflex coughing, and the expelled mucus is caught in the meshes of the gauze.

A small point, but it is generally taught to students and nurses, that the temperature is 1° higher in the rectum than in the mouth. With tested thermometers, taking the temperature in these two places simultaneously in twelve cases I have obtained the following results: In four cases the rectum was higher by 0.2, 0.2, 0.3 and 0.6°; in five cases the temperature was exactly the same in the two cavities; while in three cases the mouth was higher by 0.1, 0.2 and 0.2°.

Two photographs taken by Mr. Dodd of cases in the children's clinic were also shown.

(*a*) A case of rachitis in a child two and a half years with double coda vara, showing the customary attitude of the child in repose, with both legs lying straight up beside the trunk, the soles being applied to the sides of the face.

(*b*) A case of congenital syphilis, showing marked prominences on the tibial.

Reports of Societies.

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY.

W. E. PAUL, M.D., SECRETARY.

MEETING of April 21, 1904, the President, Dr. G. Alden Blumer, in the chair.

DR. J. W. COURTNEY presented a case of

BILATERAL FACIAL ATROPHY.

I was not present at the last meeting when Dr. B. T. Burley[1] showed his case of bilateral idiopathic facial atrophy, but by the merest chance I came across a case of the same sort a few days ago, and have brought it here to-night to show to you. This little girl, who is now about twelve years of age, was normal in every way up to the age of three. The photograph I am about to pass round, which was taken about that time,

[1] BOST. MED. AND SURG. JOURN., April 14, 1904.

certainly shows no evidence of facial abnormality. Shortly after the age of three the child's face began to take on a pinched and shrivelled look, and the parents feared that the child was going into consumption. They consulted many doctors without avail, marveling themselves all the while that the supposed emaciation should remain confined to the face, as in fact it did. For three years the wasting of the face went on and then appeared to come to a standstill, leaving the child about as you see her to-night.

You will observe that her body is fairly well nourished and that its nutrition is in striking contrast with that of the face, which looks pinched, sunken and senile. On examination the atrophy is seen to be bilateral, and more or less symmetrical, and to involve mainly the skin and subcutaneous tissue, apparently sparing the muscles. There is, furthermore, no demonstrable implication of the jaw or of the tongue, although several of the teeth have come out without obvious cause.

As I am going to report this case *in extenso* later, I shall say no more about it at the present time, but simply have the patient walk about for your inspection.

DR. P. C. KNAPP: If we can judge from this case which Dr. Courtney kindly permitted me to examine the other day, and from the pictures which Dr. Burley has shown, and which other observers have published, there does not seem to be any very marked involvement of the bones in bilateral facial atrophy. In unilateral atrophy, however, the bones seem to be rather frequently involved. I saw a young man of seventeen about twelve years ago, referred to me by Dr. J. T. Bowen, who had unilateral atrophy of two years' duration. The entire half of the face, the cranium and the ear were smaller on the left side. There was a band of whitish, smooth, sclerotic skin starting at the root of the nose and extending upwards, close to the median line on the left side of the forehead, 4 cm. in width and about 12 cm. in length, extending into the hairy scalp to within 3 or 4 cm. of the vertex. The bone was wasted distinctly under this atrophied skin. In another case also the forehead was involved, contrary to the rule stated by Dr. Burley. In this case, and still more in the cases with great atrophy of the bones, it seems doubtful whether paraffin injections would be of much service.

DR. H. R. STEDMAN read a paper entitled

A CASE OF MORAL INSANITY WITH REPEATED HOMICIDES AND INCENDIARISM AND LATE DEVELOPMENT OF DELUSIONS.

DR. C. P. BANCROFT: Dr. Stedman's very interesting report of this somewhat celebrated case arouses anew the old question as to whether a true moral insanity can exist. Is it possible for the moral faculties alone to be affected while the intellect remains unimpaired? Personally I have never seen a case of what seemed to me pure moral insanity. Those cases under my observation that seemed to suggest possible involvement of the moral faculties without intellectual impairment have, on further and closer study, disclosed weakening of the higher intelligence. It has always seemed to me that the old metaphysical division of the mind into faculties must have been a determining factor in the original diagnosis of "moral insanity." The partitioning of the mind into faculties tends to mislead the diagnostician when attempting to reconcile them with pathological processes.

The mental faculties have no very definite demarcation, the one from the other, undoubtedly have no specific brain area in which they are organized and owe their existence to the purely arbitrary conclusions of the metaphysician. Cases do occur in which apparent impairment of one faculty precedes a later involvement of other faculties and demonstrate the solidarity of mind. A case in question under my own personal experience occurs to me. A young woman of fair heredity, with advantages of good early training and environment, at about the age of puberty developed the most perverse and unaccountable sexual appetite. At the age of twenty she so degraded her family that the benefit of the doubt was given her, and she was pronounced insane. For a year she remained under my care, not evincing the slightest sign of intellectual disturbance and stoutly asserted that if she desired to lead an immoral life it was her own affair and that neither I nor her relatives had any legal right to deprive her of her liberty. I began to feel that my further detention of her in the hospital would be untenable and was on the point of ordering her discharge when she broke down into an attack of acute mania. These attacks have occurred ever since with regularity about once a year, and more or less mental impairment began to declare itself. This was undoubtedly a dementing psychosis from the beginning. Moral impairment was the one early symptom manifest, followed by marked psychic explosions later. Nevertheless, could a more minute analysis of this individual's mind have been made in the earlier stages of the psychosis, I believe that a beginning general impairment of the intellect could have been detected, such as weakening of the will, the judgment and the feelings.

I have often thought the term "moral imbecility" more justifiable than "moral insanity." Certainly, cases do occur in which the moral nature seems to be so dwarfed and rudimentary from early childhood as to lead one to infer that its development is impossible. Jesse Pomeroy appears to have been a notable illustration of such a condition. Rarely does it occur that a person, whose mental development has been normal, has an attack of moral insanity without intellectual impairment. The very interesting case of J. T., while for a long period manifesting only moral perversity, certainly at the present time discloses marked intellectual disturbance. Her case appears to be a dementing psychosis, the primary symptoms of which were morbid impulsions, moral obtundity, followed at the present time by delusions, hallucinations and intellectual impairment. The latest manifestations complete the picture of what at first seemed a most obscure case. They demonstrate anew the solidarity of mind and the unwisdom of making a too early diagnosis of "moral insanity."

DR. EDWARD COWLES: Dr. Stedman's report of this important case has been made especially interesting by his careful study of the subject. There are undoubtedly many cases in which intellectual capacity even to a high degree exists in association with more or less complete deficiency of the moral sense that characterizes the class of persons called degenerates. We see all degrees of this deficiency in youth and adolescence. In many cases it can be recognized as simply an indication of backward or unequal development, and may be outgrown; in other cases there is arrest in this regard, causing permanent defect. The term "moral imbecility," as implying the absence of qualities of character never possessed, seems to me to be a proper one to describe such a general characteristic. This term being more generic in its meaning is better than "moral insanity," which seems to imply a definite form of mental disease, while the moral defect to which it refers is only one of the general variations from the normal mental balance in most cases. I recall a number of young cases that quite outgrew this defect as they came to adult life; several of these were pronounced hospital cases that practically recovered,

or were greatly improved under several years of the restraint and discipline in the period of adolescence.

A great deal depends upon the circumstances under which such young persons grow up, and upon their accidental experiences which may be the starting-points of peculiar forms of excitement that create an inclination to repeat them, through curiosity or liking. It would be interesting to know how it would have turned out with this young woman if she had never had the experiences of a nurse and become familiar with the effects of drugs and seeing the unusual manifestations of conditions of sickness and death. These things that suggest unanswerable questionings in some minds might have excited unnaturally an abnormal mind. On the same principle she might have developed a propensity for stealing, or excesses in sexual misconduct under the influences of a favoring environment and experiences. It appears to me that her history shows fundamental inherent defects consistent with considerable intellectual capacity; that the criminal acts being at first carefully concealed and later more frequently and recklessly committed, mark the regular course of a mental disease from its beginning to its latest development in a pronounced form of insanity.

Dr. Walter Channing said that he regarded Dr. Stedman's paper as a very valuable contribution to medico-legal literature. There was no question in his mind that J. T. was insane and that in the true sense of the word she was a degenerate, even though no physical stigmata of degeneracy had been discovered. The mental stigmata as detailed in the evidence in the report just presented were even more important. By what name the disease of which she was the subject should be called is a matter of some difficulty to determine. He regretted that Dr. Stedman had revived the use of the term "moral insanity," which had formerly been a sort of waste basket in our courts for all sorts of doubtful mental diseases to be emptied into. He himself never made use of it in testifying, and hoped that it would not again be introduced into our courts. The form of disease described seemed to him to be closely allied to one of the earlier stages of paranoia, but what Dr. Stedman calls moral insanity and paranoia have much in common. He was strengthened in this opinion by the history of the woman's case since she had been in the hospital, which had undoubtedly developed into real paranoia. This disease often is very slow in its progress, passing through various stages, and it might be that the latest one had now arrived. He did not agree with Dr. Folsom that alienists are multiplying names for the various forms of insanity, nor the danger of including too much within the limits of what could be called mental disease. Many of the old names under earlier systems of classifications had been dropped and others better adapted to our present knowledge of mental disease adopted. There has therefore been really a diminution rather than an increase.

It must be remembered that sanity was an impossible thing to define; as Hirsch had said, it consists substantially in the well-proportioned development of mental attributes, but there might be great variation within pretty wide limits and still indicate no insane condition. Knowledge of insanity was acquired from experience. An opinion might be given with almost unerring conviction, and yet the form of insanity be very difficult to specify with exactness. Far too much importance was attributed to names which might be misleading. The point was to determine if there was an undoubted departure from the normal. He would say in conclusion that he should be sorry that Dr. Stedman had been employed as an expert in this case, if he was to be the means of reviving in court practice the expression "moral insanity."

Dr. G. L. Walton: The applicability of the term degenerate in this connection only serves to emphasize the importance of a substitute for this word in referring to mild deviations from the average normal type. Whether this case should be classed as insanity during the period under consideration is an open question, notwithstanding the fact that mental unbalance of another type has evidently appeared during confinement in the asylum.

With regard to the general question of crime and insanity it is true that the fear of public opinion should not prevent the diagnosis of insanity in the criminal when this diagnosis is clear, but there is danger that in relieving criminals of legal responsibility, arguments may be made to serve which would be given little weight as bearing on the question of depriving an ordinary individual of his liberty. If a criminal has shown himself capable of properly registering impressions, and of formulating appropriate lines of conduct based upon those impressions, and of carrying out those lines of conduct, due allowance being made for his education, surroundings and social station, the mere fact that he does not carry out such lines of conduct, and that he expresses no remorse for this failure, is not necessarily evidence of insanity. Very strong evidence should be added, it seems to me, of mental defect other than moral, before he should be deemed legally irresponsible.

Without claiming ability to formulate a plan for the management of the many morally oblique and criminally reckless individuals who are working havoc in society and causing pecuniary loss and shame to their relatives and friends, I may venture to suggest that in applying too fine an analysis to their mental processes we are in danger of losing sight of the interests of the community and of granting certificates of immunity on a scale whose liberality is bound eventually to bring about a reaction on the part of the public, whose rights we are in danger ourselves of ignoring in our pursuit of the absolute in science.

Dr. C. A. Drew: I feel a deep appreciation of the privilege of having heard Dr. Stedman's paper. The case is certainly not an ordinary one. The moral imbecile is a fairly common character at the State Asylum for Insane Criminals. But it seems to me that J. T. was, or is, at least, more than a moral imbecile. The moral imbecile as we see him is apt to remain merely a moral imbecile to the end of the chapter. Hallucinations do not seem to be a necessary part of his symptom complex, and what irrational ideas he has are, as a rule, hardly fixed enough to be called delusions. The great majority of these cases of ours could be classed more fittingly as "deviates," if you will accept Dr. Walton's term, which I think fits the moral imbecile better than the word degenerate. But J. T. seems to be a degenerate. It seems to me as if the mental deterioration has been too rapid and the mental states too quickly alternating to call the case paranoia, if we use that term as synonymous with primary delusional insanity. It looks to me as if the case was one of the rapidly dementing psychoses, although moral imbecility with perverted impulses and instincts might have explained most of the early symptoms.

Dr. P. C. Knapp: Although it is doubtful whether we can regard "moral insanity" any more than mania and melancholia as a distinct disease, the term is certainly useful as applied to a certain fairly definite symptom group. Various cases come each year under my observation presenting the symptoms usually classed under this heading. There is almost invariably

some intellectual failure, but at first sight the patient appears to be bright and intelligent, and sometimes he has a precocious smartness. Careful observation, however, usually reveals considerable intellectual defect.

Dr. Stedman's report, based on so long study and observation, leaves no doubt as to the insanity of this case, which has now been fully confirmed by the subsequent course. The fact that this patient had a copy of Krafft-Ebing's "Psychopathia Sexualis" has been brought forward as a proof of her feigning, but the diagnosis, as I understand, was not based upon the existence of any sexual perversion, and the alleged form of sexual perversion described by the patient is not mentioned in Krafft-Ebing.

DR. ARTHUR V. GOSS: I can add nothing to the masterly analysis of this case as presented by Dr. Stedman. When she was admitted to the Taunton Insane Hospital the medical staff was, if anything, inclined to the opinion that she was responsible for her acts. They all studied her case independently and almost without consultation, with the result that each and all were convinced of her mental unsoundness before the development, or at least the appearance, of delusions. At present she is suffering from delusions of persecution and poisoning with hallucinations of hearing.

DR. H. W. MILLER: I agree in the main with the reader's conclusions. The diagnosis depends upon the question as to whether one is willing to accept the entity of a disease which involves only the feelings and affections without involvement of the other intellectual faculties. This condition has been called moral insanity. In this case in spite of the absence of anatomical stigmata of degeneration I believe that there existed a congenital defect, and that her untruthfulness, dishonesty and criminal acts are an outcome of this defect. I do not think that there has been any psychosis grafted on the above condition. Owing to her general unreliability I think we are justified in doubting the presence of hallucinations, though it certainly looks as though she has delusions.

During her hospital residence she has shown nothing inconsistent with the diagnosis of moral insanity; I have been for some time firmly convinced of her insanity.

DR. E. STANLEY ABBOT: It may be of some interest to those present to know that J. T. nursed in two families with which I am intimately acquainted, and that she was the nurse in attendance during the last illness of each. In one family she had previously nursed two or three times. The impression she made upon both families, which has not been changed by the subsequent developments in her career, is of one having some of the best of nurse-like qualities. She did not upset the households into which she went; she got on well with the servants in the house; she was thoughtful and attentive to the patient in many ways; she was ready to sacrifice her own comfort and convenience to that of the patient; she was wisely sympathetic, and she showed intelligence and good sense. Such was the judgment of persons of education and discrimination.

If she could behave continuously so well as to leave such an impression on such persons, I cannot help thinking that she was able to control her conduct in relation to the persons whom she poisoned. She killed them to gratify a feeling of pleasure, as men drink or yield to other minor indulgences to gratify their pleasures, but she was under no internal compulsion. Believing as I do that it is of the essence of insanity that the insane person cannot help thinking, feeling or acting as he does, I must regard J. T. not as insane, but as criminal, and the symptoms that she now presents are due to a psychosis superimposed on a constitutional defect.

I should agree with Dr. Cowles that moral imbecility is a better term for such a condition as she appears to have than moral insanity, and moral deficiency is better still, since the word imbecility suggests intellectual deficiency, which may not be present in moral defectives. Not having heard the first portion of Dr. Stedman's paper, I may have lost some data which would make me see the case in a different light, but from what I did hear and from my own slight knowledge of the patient, I should regard her as an intelligent moral deficient.

DR. STEDMAN in closing said that the discussion showed that moral insanity had well borne out its reputation as the "red rag" of psychiatry. He enumerated a number of the foremost modern authorities on mental diseases, who not only classify moral insanity as one of them, but who devote special chapters to its consideration. It was rather striking, too, that not only the name but the conception of the disease or defect had, unlike so many mental conditions which were once thought to be entities, undergone little or no change. Its study is much simplified by separating secondary or symptomatic moral insanity, of which the adolescent case cited by Dr. Bancroft is evidently an example, from the true primary and congenital form represented in J. T. Whether we label the condition a disease or a defect seems of less consequence when we consider the hereditary, congenital origin of degeneration-insanity in general and the fact that there are many points at which imbecility proper and paranoia, which has been called a "partial imbecility," approach each other.

It is common knowledge that the habit of wrong doing may be acquired to such an extent that crimes excite no feeling. This applies, however, to the insane as well as to the sane criminal. But the instant, instinctive readiness with which the first step in crime is taken, the great rapidity with which the propensity becomes firmly established and the extremes of crime and bestiality reached are identifying marks of degeneration-insanity of this order.

[The view that we are dealing in J. T.'s case with a dementing psychosis is hardly tenable, as her mind has lost in all this time little of its acuteness. On the other hand she has developed the intellectual perversion without appreciable loss of mental *power*, that is: dementia, which is only found among insanities of degeneration. As to the danger of too much liberality in granting certificates of insanity in criminal cases we should say that before becoming anxious about a remote contingency, to our mind far from probable, it would be well to turn people's attention more often to the fact that many so-called criminals are regularly convicted only to be found insane in a short time and transferred to the asylum, for want of preliminary expert examination of their mental condition. It is such methods as this which help to substantiate McPherson's belief that the law has hitherto certainly erred on the side of severity and has hanged ninety-nine irresponsible persons for one responsible person who has escaped on the plea of insanity.]

THE Missouri State Medical Association, according to the *Medical Record*, has decided to publish its transactions in the form of a monthly medical journal and the initial number of the *Journal of the Missouri State Medical Association* appeared on July 1. Dr. C. M. Nicholson is editor, assisted by six collaborators.

AMERICAN GYNECOLOGICAL SOCIETY.

TWENTY-NINTH ANNUAL MEETING, HELD IN BOSTON, MASS., MAY 24, 25 AND 26, 1904.

(Continued from No. 2, p. 50.)

SECOND DAY. — (Continued.)

SYMPOSIUM ON INJURIES TO THE PERINEUM.

THE PREVENTIVE TREATMENT OF PELVIC FLOOR LACERATIONS.

DR. J. CLIFTON EDGAR of New York read the first paper. The most important part of the management of the second stage of labor was the prevention of pelvic floor lacerations; lacerations of the fourchette in primiparæ, and superficial tears about the vulvar orifice in both primipara and multipara, often occurred, were often unavoidable, and usually readily healed with simple asepsis. Deep lacerations were avoidable in normal, ordinary cases of labor.

The factors which tended directly or indirectly to produce pelvic floor lacerations were numerous, but for convenience he arranged these in three major classes. These were concisely stated as (1) too rapid expulsion of the fetus, so that tearing instead of stretching resulted. (2) Relative disproportion in size between the presenting part and the parturient outlet. (3) A faulty mechanism of labor, whereby the larger circumference of the head and shoulders than necessary passed through the parturient outlet.

From an extended clinical experience, he could speak most enthusiastically of the preliminary digital stretching of the vulvar outlet in primiparæ, and especially in elderly primiparæ, as a prophylactic measure in perineal protection. The author then discussed episiotomy, head delivery, and cleidotomy. Regarding shoulder delivery, the author firmly believed, from years of careful clinical observation, that the posterior shoulder was responsible for many instances of deep, pelvic floor laceration. Furthermore, that moderate ruptures caused by the passage of the head were often increased and rendered serious by the subsequent passage of the posterior shoulder.

He had been most successful in the following method of shoulder delivery, and either the lateral or dorsal posture of the patient could be used at will. This method was not new:

(1) The delivery of the shoulders was delayed, if possible, until nearly complete rotation of the bisacromial diameter had taken place. (2) The fetal head was taken in the hand and gently raised or pushed, so as to bring the anterior shoulder well up behind the symphysis, thus giving the cervico-acromial diameter of the fetus at the outlet instead of the bisacromial. (3) The posterior shoulder was now allowed to pass out spontaneously, and whenever possible, manual extraction should be avoided, as this increased the risk of perineal rupture. (4) During the detention of the anterior shoulder behind the symphysis, the fetal hand of the opposite arm lying across the fetal chest would usually soon appear in the vulva. He had found that delivery might be safely assisted by slowly flexing this forearm and arm out through the vulva and thus delivering the posterior shoulder by slight traction on the posterior arm. (5) Should the foregoing be impracticable, and delay in the expulsion of the posterior shoulder occur, he had found gentle traction upon the head, the fingers encircling the neck, to be preferable to traction with a finger in the axilla. (6) Should there be delay in the delivery of the anterior shoulder, after expulsion of the posterior, it was best remedied by making traction directly downwards, with the hands placed on the sides of the head, taking care not to make too great pressure on the perineum. As a last resort, traction might be made by a finger in the axilla.

IMMEDIATE REPAIR OF LACERATIONS OF THE PERINEUM, WITH SPECIAL REFERENCE TO PLACING THE SUTURES BEFORE THE LACERATIONS OCCUR.

DR. LAPTHORNE SMITH of Montreal spoke of the importance of closing up even small tears of the perineum, so as not to leave raw surfaces for septic absorption. It was important to close large tears so as to retain the function of the pelvic muscles. The best time to put in these stitches was just before the head pressed on the perineum, while the patient was anesthetized, and before the parts had lost their relative positions. With the left finger in the vagina and the thumb in the rectum, a large perineum needle on a handle was passed just under the vagina, threaded with silkworm gut; the two or three stitches hung loosely in a Pean forceps until the placenta had been delivered, when they were quickly tied, bringing the parts exactly together as they were before the tear.

(To be continued.)

Recent Literature.

Graves' Disease, With and Without Exophthalmic Goitre. By WILLIAM HANNA THOMSON, M.D. LL.D. 8vo. pp., vi, 143. New York: William Wood & Co. 1904.

In the volume before us the author maintains the thesis that Graves' disease is a toxemia of gastro-intestinal origin, with well-defined symptoms, among which neither exophthalmos nor goitre is to be regarded as of chief importance, the implication of the thyroid, when it occurs, being secondary to the toxemia. This thesis is based upon a study of seventy-three personal cases, forty-four with goitre and twenty-nine without; four of these cases, two in each class, terminated fatally. The most striking symptoms are tachycardia, palpitation, nervousness, tremor, headaches, characteristic digestive disturbances, insomnia, and the fact that all these symptoms are worse in the morning. The disease is chronic, occurring in families and sometimes associated with migraine. Death is apt to be sudden from syncope. Noteworthy success has been attained by treating the gastro-intestinal disorder chiefly by a long-continued milk diet. Thyroidectomy is denounced. It is apparent that these opinions as to the nature of Graves' disease are radically different from those that have obtained in recent years, since our enlarged knowledge as to the functions of the thyroid led to the belief that Graves' disease was of thyroid and not of vasomotor origin. That cases of Graves' disease occur without exophthalmos or goitre must be admitted, and gastro-intestinal disturbances are common in all types of the disease. Whether the author's views will ultimately be accepted is uncertain, but they are based on a wide experience of the disease, and the present volume is one that must be considered in future study of the subject.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

WAS JANE TOPPAN RESPONSIBLE?

IN another part of this issue we publish the detailed report from Dr. H. R. Stedman's pen of the medical history of Jane Toppan. Dr. Stedman, it will be remembered, was one of three experts, the others being Dr. H. M. Quinby and Dr. George F. Jelly, appointed by the Court to investigate the mental condition of the nurse, Jane Toppan, who had been indicted on the charge of murder. The extraordinary character of the crimes charged against her, and the widespread publicity given to the events which finally led to her arrest, combined to render the case one of the most widely discussed of recent years. It is, therefore, a matter of great interest that an authoritative statement of her life and the development of her disease has finally been given.

It was natural that difference of opinion should have existed regarding the question of her criminality and responsibility. In such cases the subtle and uncertain distinctions between sanity and insanity, and between moral responsibility and deliberate crime, are peculiarly difficult to determine. No greater burden could well be placed upon an expert's shoulders than this. The decision reached by the gentlemen called in the case was that the prisoner was not responsible for her acts, by reason of insanity, and she was thereafter committed to the Taunton Insane Hospital by order of the Court, where she has since remained under the conditions described in Dr. Stedman's paper.

Commenting on the case editorially at the time of the trial in 1902, we said: "The medical expert's question of mental unsoundness settled, there still remains the personal equation and the question of accountability. We shall await with great interest the forthcoming analysis of the evidence in this case and the expert statement, which we are promised, of the medical opinions formed and of the facts upon which those opinions are based. In the meantime, we shall not attempt to express our opinion on the question of Jane Toppan's responsibility."

The events of her hospital life, as since developed, can leave no doubt of her mental unsoundness, and we think also none of her lack of accountability as judged by ordinary standards. The evidences of mental decay have been increasingly apparent, and there can be no question that her proper classification is among the insane. In view of the present condition and its development, the existence of mental unsoundness extending over a long period of years is altogether probable, and undoubtedly fully justifies the expert opinion delivered at the time of her trial.

It must, however, be distinctly remembered that the difficulties of discovering the means used by her were such that detection of her implication in the deaths of her victims was almost impossible. Her method of administering deadly drugs was such that the patient was usually wholly unaware of what he or she was taking. In the second place, a physician was usually not summoned until the patient was moribund; and, finally, her method of combining drugs in such a way that their action gave rise to unusual and perplexing groups of symptoms, rendered it at times impossible to determine the real nature of the illness. Attempts to determine the cause of death by post-mortem examinations were uniformly opposed by the nurse. This combination of circumstances certainly is sufficient to explain her long immunity from detection, and under the circumstances we are forced to the conclusion that her earlier detection, enjoying as she did the confidence of those with whom she was associated, was well nigh impossible. Only the final act of her career, which led to the death of four patients in one family, was sufficiently extraordinary to lead to the investigation which resulted in her arrest.

The case will soon pass into history, but not, we trust, without having taught its unique lesson.

THE VISIT OF PROFESSOR HOFFA.

IN spite of our anti-imperialistic contemporaries we must admit there are certain advantages which come to the inhabitants of a well-advertised world power. Now that Secretary Hay is supposed by some Continental observers

to hold the destinies of the Pacific and the future of the Orient in his portfolio, and is publicly honored by the French Government for his efforts to preserve the peace of the world, it is natural that gifted foreigners should wish to examine at close range the conditions of a country which, though not old, in its influence, as our poet tells us, "was never young." Many of our readers may recall one of Mr. Lowell's brilliant essays, "A Certain Condescension in Foreigners," satirizing a common attitude of the visitors of that time. Those who come among us now "taking notes" bring a different spirit, though fortunately they still are critical, giving us often the benefit of their "impressions" to temper our growing tendency toward self-content, which comes with and is the peril of prosperity, as complacency is the *arcus senilis* of national character. It is of the greatest advantage to see ourselves as others see us when the "others" are unusual and remarkable men. The English Commissioners who have studied us, the French literary critics who have lectured to us, have all brought gifts without giving us reason to fear them, and their example has been followed within the last few years by several most distinguished Germans, who have brought to us their example of thorough skill and brilliant achievement.

Professor Hoffa, our most recent visitor, came with a commission from the Berlin Government to examine our municipal ambulance systems and report upon them. He timed his visit, however, so as to present a paper at the meeting of the American Orthopedic Association at Atlantic City. His experiences in the treatment of congenital dislocation of the hip has been followed by an unusually high percentage of success, as might be expected from the fact that he was one of the early investigators in the subject, and has devoted to it much study, unusual skill, thorough training and a broad, intelligent spirit of eclecticism rather than that of a partisan of a special method. Manipulative reduction he practices in the less difficult cases, but when this is impracticable he advises opening the capsule, deepening the acetabulum, when shallow or filled with fibrous tissue, and a careful replacement of the head. The necessary dissection is neither extensive nor destructive and the method leaves nothing to chance.

The treatment of paralytic deformities by tendon and muscle transference has been brought in Germany to a valuable state of efficiency, and Dr. Hoffa gave, while here, a demonstration at the Children's Hospital of his admirable operative skill in the employment of this method.

Unfortunately the harvest of congenitally dislocated hips had been so thoroughly garnered in this community that no case could be found for his ministrations. In New York, Philadelphia and Chicago, however, he was able to demonstrate his method of operative reduction.

Let us hope that our country will continue to "expand" if thereby we can attract to ourselves such agreeable and valuable visitors.

PLAGUE IN THE TRANSVAAL.

A REPORT has recently been published giving certain details of a recent outbreak of plague in the Transvaal, to which the *British Medical Journal* alludes in an abstract of the report and also editorially. It appears that in 1903 pneumonia gave origin to a scare regarding plague, but it was afterwards determined that at least the great majority of cases was due to a septicemia induced by streptococci or pneumococci. A later outbreak of plague, however, has led to the assumption that certain of these cases of so-called pneumonia were in reality plague.

On March 18 of this year it was announced that certain Asiatics living in the "Coolie" location were apparently ill with pneumonia. The following day five corpses and twelve sick persons were found in one house. In three of these cases, together with pneumonic consolidation, microscopic examination disclosed organisms of the morphology of plague bacillus, and the same organism was also found in the sputum of a Coolie suffering from pneumonia. A cordon about this locality was thereafter made and a house to house inspection within the insanitary area instituted. Twenty-six deaths were shortly recorded, all presenting symptoms of pneumonia and all showing the presence of plague bacilli. The plague staff was enlarged, additions were made to the numbers of rat catchers, and drastic measures were forthwith adopted. In the first place the plague committee transferred the entire population in the "Coolie" location to a segregation camp, numbering 3,100 persons. Twenty-four days after this transfer but one death had occurred. The area of infection was surrounded by a galvanized wire fence, animals found in it were killed, and the entire place burnt to the ground. Various general measures were taken regarding suspects, disinfection and medical examinations with most gratifying results.

The origin of this epidemic has not been

definitely discovered. The final explosive outbreak is held to have been due to the fact that plague was masked by the coincident presence of pneumonia in many cases. The brief history of this epidemic and its vigorous suppression serves as an interesting commentary on the admirable methods now available for checking a disease which, under unfavorable conditions, quickly becomes a menace of great moment. Such incidents as that narrated leave no doubt that plague, like many other infectious diseases, may under ordinary conditions be suppressed.

Commenting on the event editorially, the *British Medical Journal* expresses the conviction that the public health departments of the Transvaal and Johannesburg fully appreciate that the danger of a recurrence cannot be by any means neglected. It seems that the infection was imported into the Transvaal by rats in forage, and even if domestic rats and other domestic animals are not still infected, the risk of further importation cannot be ignored.

MEDICAL NOTES.

REGISTRATION OF DENTISTS. — The Massachusetts Board of Registration in Dentistry has passed fifty-five out of one hundred and three candidates desirous of practising in this state.

CHAIR OF HYGIENE, BERLIN. — It is announced that Prof. Georg Gaffky of the University of Geissen has accepted Professor Koch's chair in hygiene at the University of Berlin, Professor Koch having resigned the directorship of the Berlin Hygienic Institute. Gaffky was Koch's earliest assistant, and it is said to have been Koch's wish that he should succeed him as director of the well-known hygienic institute. His work has been largely experimental in connection with various bacteriological problems.

TUBERCULOSIS DISPENSARY, WESTERN RESERVE MEDICAL SCHOOL. — It is proposed to establish a dispensary for the special treatment of tuberculosis in connection with the medical school of Western Reserve University. One of the chief functions of the dispensary is prophylactic. Those infected with the disease will be registered; houses occupied by consumptives located; education of the people in matters of hygiene prescribed; visits to the school made; and instructions to those having the disease instituted.

HONORARY DEGREES FOR MEDICAL MEN. — The *Medical Press* makes the following statement: "The honorary degree of D.Sc. will be conferred upon the following members of the profession at the meeting of the British Medical Association at Oxford on July 27: Dr. T. C. Allbutt, F.R.S.; Mr. Andrew Clark, F.R.C.S.; Dr. Thomas D. Griffiths, President of the British Medical Association; Mr. Jonathan Hutchinson, F.R.S.; Sir William MacEwen, M.D., F.R.S.; Sir Patrick Manson, K.C.M.G., M.D., F.R.S.; Sir John W. Moore, M.D.; Dr. William Osler, F.R.S.; Dr. Thomas G. Roddick, M.P. (Canada), a former President of the British Medical Association.

BELLEVUE HOSPITAL'S FAMOUS WARD 32. — According to the *New York Medical Journal* in the last nine years there have been 51,000 alcoholic patients at Bellevue Hospital, not counting the repeaters. Of this number, 66% were between thirty and forty-nine years of age. A series of 125 cases has been studied, showing that as a rule male drunkards live longer than female. Seventy-five per cent of all chronic alcoholics have fatty degeneration of the liver. Many have brown atrophy of the heart. The kidneys are never normal. Fifty per cent of the drunkards have gastritis. By the coating of the tongue and the character of the tremor the length of a spree can be accurately determined. The drunkard often "sees things," but rarely has his sense of smell impaired. Patients who drink absinthe are particularly liable to convulsions.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, July 20, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 31, scarlatina 9, typhoid fever 9, measles 41, smallpox 0.

GRADUATES IN MEDICINE, HARVARD MEDICAL SCHOOL. — At the recent commencement exercises of Harvard University, 130 students received the degree of M.D.

NEW YORK.

TRAINING SCHOOL OF BETH ISRAEL HOSPITAL. — The graduation exercises of the first class, twelve in number, to complete the course at the training school for nurses connected with Beth Israel Hospital, were held on July 12. This Jewish hospital, which is situated in the crowded tenement district of the lower East Side and was begun fifteen years ago in a very humble way, now has a capacity of one hundred and thirty beds, and has recently acquired property adjoining the hospital building on which to establish a nurses' home.

Inspection of Milk. — The Health Department inspection of milk is properly very rigid at this season of the year. Out of 869 shops selling milk which were visited by the inspectors during the thirty days ending July 8, 365 were found where there were connecting rooms used for living purposes. One hundred were found where the milk on sale was at a higher temperature than the law permits, but where there were no connecting rooms, while ninety-six cases were found of violations of the law as regards both temperature and connecting rooms. Altogether, in 64½% of the shops visited the ordinances were found to be violated in one way or another.

Vacation Schools and Playgrounds. — The ten weeks' summer session provided by the Department of Education opened on July 11. This year there are thirty-nine vacation schools and eighty-four playgrounds operated by the department. Nature study is taught as a general subject by forty practical experts, and one thousand teachers are employed in instructing the children in manual branches of various useful kinds, gymnastics and kindergarten. In some of the playgrounds the planting and care of vegetable and flower gardens will be taught. Altogether, the vacation school system would seem to be productive of great good, mental and moral, as well as physical, to the children of the poor. A new departure this year is the utilization of eleven schoolhouses with flat roofs, on which free band concerts are given each night for the general public.

Commission to Investigate Pneumonia. — In consequence of representations made by Dr. Darlington, President of the Board of Health, in regard to the unusual prevalence, for this season of the year, of pneumonia, the Board of Estimate and Apportionment, at a meeting held July 15, made an appropriation of $10,000 to defray the expenses of an expert commission to investigate the subject and devise means for the checking of the disease. The selection of the members of the commission is left with Dr. Darlington, and they will be appointed within a short time.

Obituary.

ISRAEL THORNDIKE DANA, M.D.

Israel Thorndike Dana was born in Marblehead, Mass., June 6, 1827. He died in Portland, Me., April 13, 1904. He was the youngest of fourteen children of Rev. Samuel Dana. His mother was Henrietta, daughter of Dr. Richard P. Bridge.

After receiving the degree of M.D. from the Harvard Medical School in 1850, he spent two years in post-graduate study in Paris and Dublin. Following the advice of Dr. Pearson of Salem, in June, 1852, Dr. Dana began practice in Portland. His service to this community at the time of his death antedated that of any other physician.

He was one of the founders of the Portland Dispensary. In 1856, together with Dr. William C. Robinson and Dr. Simon Fitch, he established the Portland School for Medical Instruction. From 1860 to 1862 he was professor of Materia Medica at Bowdoin College; and from 1862 to 1897, excepting an interval between 1870 and 1880, he was professor of the Practice of Medicine at Bowdoin College. Dr. Dana was an active force in the founding of the Maine General Hospital. He served for twenty years as one of the visiting physicians, and afterwards as a consulting physician who was actually consulted. In 1868, he was president of the Maine Medical Association. He was one of the first members of the Harvard Medical Alumni Association to hold the office of vice-president. Dr. Dana was a charter member of the Association of American Physicians, and a few years before his death was made one of the honorary members.

Possessed of the talent which these places of honor and usefulness imply, Dr. Dana's advice as a consultant was widely sought. His specialty, if he had one, was internal medicine, his professional interest directing itself particularly to diseases of the heart and lungs. A keenly-observant colleague says: "The Doctor Dana of thirty years ago was an alert and accurate diagnostician, — a model of what a resourceful physician ought to be."

Of Dr. Dana's ten children, three died in infancy. The vigorous and useful lives of three others, after reaching maturity, were brought to a sudden close. One of them, William Lawrence Dana, was a surgeon who well deserved paternal pride for what he was, and for what he seemed about to be.

Dr. Dana's father, his father's father, and two of his father's brothers were Congregational clergymen. Inheritance, training and habit put into his life a large endowment of orthodox religion. It has been remarked that his own leadership in medicine received the same sort of tacit recognition which, in old New England times, it was customary to pay the parson. Dr. Dana was a fine example of a certain type of Puritan dignity, mellowed in him, perhaps, by the two years of life among people of Celtic race. At times his suavity of manner was fortitude in action. A presuming person or an unethical transgressor found him an unsafe mark. His rebuke came at the effective moment. His voice was still urbane, but the words were like bullets, and the aim was true. Representing, as it does, a life of consistent service, of distinction acquired and held by faithful endeavor, the name of Israel Thorndike Dana will long be held in honor by his children, his patients, his colleagues and his friends.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JULY 9, 1904.

CITIES.	Population Estimated, 1904.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from Infectious diseases.	Acute lung diseases.	Diphtheria and croup.	Cerebro-spinal Meningitis.	Diarrheal Diseases.

Deaths reported, 3,438; under five years of age, 1,352; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,283; acute lung diseases 233, consumption 358, scarlet fever 20, whooping cough 9, cerebrospinal meningitis 40, smallpox —, erysipelas 1, puerperal fever 15, measles 20, typhoid fever 39, diarrheal diseases 730, diphtheria and croup 52.

From whooping cough, New York 6, Chicago 2, Philadelphia 1. From measles, New York 15, Chicago 1, Philadelphia 1, Pittsburg 1, Boston 1, Plymouth 1. From cerebrospinal meningitis, New York 34, Pittsburg, 1 Boston 1, Brockton 1, Chelsea 1, Everett 1, Quincy 1. From typhoid fever, New York 9, Chicago 4, Philadelphia 7, Baltimore 1, Pittsburg 16, Boston 2. From erysipelas, New York 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending June 25, the death-rate was 13.2. Deaths reported 3,867; acute diseases of the respiratory organs (London) 64, whooping cough 84, diphtheria 48, measles 180, smallpox 4, scarlet fever 27.

The death-rate ranged from 4.7 in Willesden to 22.3 in Birkenhead; London 12.8, West Ham 10.5, Brighton 17.3, Southampton 10.2, Plymouth 11.4, Bristol 13.2, Leicester 10.7, Nottingham 13.6, Liverpool 17.8, Bolton 9.5, Manchester 17.3, Salford 16.9, Bradford 14.6, Leeds 12.4, Hull 13.8, Sheffield 11.2, Cardiff 10.4, Rhondda 13.6, Wigan 13.3, Merthyr Tydfil 15.8, Handsworth 13.1, Stockport 18.3.

METEOROLOGICAL RECORD.

For the week ending July 9, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING JULY 16, 1904.

H. D. WILSON, passed assistant surgeon. Detached from the "Vicksburg" and ordered home to wait orders.

G. L. ANGENY, passed assistant surgeon. Orders of March 16, modified; ordered to duty at the naval station, Culebra, W. I., with additional duty with the Marine Detachment at that place.

T. C. CRAIG, surgeon. Retired, relieved from duty as member of a committee for fixing a standard for diphtheria antitoxin, under orders of June 30, 1902.

J. M. STEELE, surgeon. Detached from the naval station, Port Royal, S. C., and ordered home to wait orders.

W. P. KEENE, acting assistant surgeon. Detached from duty on board the second torpedo flotilla and ordered to the naval station, Port Royal, S. C.

R. A. CAMPBELL, acting assistant surgeon. Ordered to duty on board the second torpedo flotilla.

L. W. BISHOP, assistant surgeon. Ordered to the navy yard, New York, N. Y.

J. H. BACKUS, assistant surgeon. Detached from the "Annapolis" and ordered home to wait orders.

RECENT DEATH.

OTIS HENRY JOHNSON, M.D., M.M.S.S., died in Haverhill, July 16, 1904, aged sixty-three years.

BOOKS AND PAMPHLETS RECEIVED.

A Manual of Surgical Diagnosis. By James Berry, B.S., F.R.C.S. Philadelphia: P. Blakiston's Son & Co. 1904.

A Text-book of Human Physiology. By Albert P. Brubaker, A.M., M.D. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1904.

Les Fractures de l'Humérus et du Fémur par le Dr. Théodore Kocher. Traduit de l'Allemand par le Dr. Ls. Senn. Genève: Henry Kündig; Paris: Félix Alcan. 1904.

Obstetric and Gynecologic Nursing. By Edward P. Davis, A.M., M.D. Second Edition. Revised. Illustrated. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

A Text-book of Mechano-Therapy (Massage and Medical Gymnastics). Prepared for the Use of Medical Students, Trained Nurses, and Medical Gymnasts. By Axel V. Grafstrom, B.Sc., M.D. Second Edition, Revised and Enlarged. Illustrated. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

CONGENITAL DISLOCATION OF THE HIP.

I.

REPORT OF THE ORTHOPEDIC STAFF OF THE BOSTON CHILDREN'S HOSPITAL BASED UPON OBSERVATIONS ON 144 CASES.

E. H. BRADFORD, M.D., R. W. LOVETT, M.D., E. G. BRACKETT, M.D., AUGUSTUS THORNDIKE, M.D., JOHN DANE, M.D.,
Orthopedic Staff of the Boston Children's Hospital.

CONGENITAL dislocation of the hip has, until recently, been generally regarded as an incurable deformity which the wise surgeon would let alone. We have, however, been taught in the last decade that reduction of this dislocation in suitable cases is a safe procedure with a reasonable chance of success. It has been demonstrated that the necessary operation requires skill, but not skill beyond the reach of those who have followed the teachings of others and turned their attention to the details of the subject. This can fairly be regarded as an advance in surgical science. Reduction of the dislocated head, however, does not necessarily establish a permanent cure. The percentage of relapses after successful reduction has been found, even in the hands of the most skilled operators, to be unsatisfactorily high.

The following paper is based upon the experience collected at the Boston Children's Hospital and is in the nature of a report with conclusions drawn from 144 cases, 128 being treated at the hospital, treated in a variety of ways. The record of the hospital is an unusual one, as the study of the treatment of this affection has been a continued one in this institution from the time of the first attempts in this country in treating this deformity until the present when the reduction has become an accepted procedure in surgical practice. The staff of the hospital has had the benefit of consultations with that pioneer investigator, Dr. Buckminster Brown of Boston, and also with Dr. Abner Post who was the first to attempt manipulative reduction of a congenitally dislocated hip under an anesthetic, with Professor Hoffa of Berlin and Professor Lorenz of Vienna, both of whom performed operations according to their different methods. The first attempt at treatment of this affection by operative incision in this country was made at the Children's Hospital by Dr. Burrell, and the first case treated in this country by the manipulative method, now known as the Lorenz method, was at the hospital by Dr. Dane. The pathological anatomy of the affection has been studied by Professor Councilman and Dr. Nichols, Dr. Soutter and Dr. Robinson, with reports upon the pathological specimens obtained at the hospital in an epidemic of scarlet fever and diphtheria. Valuable specimens have been placed at the disposition of the staff by the courtesy of Professor Dwight and Dr. W. F. Whitney of the Harvard Medical School, and experiments upon cadavers in regard to the strength of capsular and muscular tissues have been made by members of the Orthopedic Department of the hospital. For the sake of brevity no attempt is made in this report to present the literature of the subject which has, however, been carefully studied.

The conclusions drawn from the experience gained is summarized in the following statement:

TREATMENT BY RECUMBENT TRACTION.

This method, recommended by the French and English surgeons of the middle of the last century and thoroughly applied by Dr. Buckminster Brown in a single case remaining under treatment for several years, was employed at the Children's Hospital in a few cases and in others at their homes. In one of these the treatment was applied with constant care for two years. In two cases strong recumbent traction was applied for several months continuously. In all the cases the treatment proved to be unsatisfactory. Although the limbs were drawn down to the level of the acetabulum and to the plane of its proper position, the shortened muscles being gradually stretched, all attempts at securing the head in its proper position by manipulation, mechanical devices of massage, proved failures. The benefit to be derived from the method is not commensurate with the outlay of time and discomfort demanded, and no permanent advantage was evident.

TREATMENT BY AMBULATORY TRACTION.

This method may be regarded only as possibly of use in preventing temporary shortening of the leg. The apparatus employed was a Thomas knee splint furnished with a traction foot windlass and allowing locomotion with perineal support. This apparatus was worn in one case for a year with no perceptible benefit.

EXCISION.

Excision at the hip has not been performed at the Children's Hospital for congenital dislocation of the hip. In two instances the head of the femur was sawn to alter its shape and correct a deformed condition so that it could be placed into the distorted acetabulum. In both of these cases a relapse occurred.

REDUCTION BY INCISION.

After it became evident that no cure of this deformity could be expected from traction or by the method of operative manipulation proposed by Dr. Post, attention was turned to the operative method practiced at that time by Hoffa, which was based on the supposition that no adequate acetabulum existed, and that it was necessary to create by the curette a socket to retain the replaced head. This operation, performed at the hospital first by Dr. Burrell, was repeated in several cases. One case was operated upon by Professor Hoffa when visiting Boston. No benefit followed these earlier operations. Various incisions were tried and various methods of deepening the acetabulum by drills, gouges,

surgical engines, etc., employed. The defects of the earlier operations done before 1890 lay partly in the inadequate methods used in stretching the adductor and hamstring muscles. After it had been learned that these muscles could be stretched without difficulty, and that in most cases a satisfactory acetabulum existed, the operation of reduction by incision became much less difficult and was performed in a number of cases. In the greater number of cases of treatment by incision the anterior incision was used, separating the gluteus medius from the tensor vaginæ femoris, exposing the capsule which is opened and later freed from its femoral attachments. After the upper part of the capsule was opened a director was passed into the acetabulum, the capsular construction divided and the portion of the capsule covering the acetabulum carefully preserved and placed around the femoral neck. The curette was used to deepen the acetabulum in only a few cases.

The immediate result of this operation was satisfactory in a large number of cases. There was but little shock, sepsis was prevented and as a rule the wound healed without difficulty. In fully half the cases healing by first intention took place. Although the wound was necessarily deep, in no case was serious sepsis encountered. Attempts were made to stitch the capsule around the head to form an artificial cotyloid ligament. This appeared to be successfully done in several instances. In one of the pathological specimens, from a child who died of whooping cough six months after operation by manipulative reduction of one hip with failure and successful incision in the other, it appeared that no satisfactory reduction would have been possible, without incision and division of the capsular neck. Incision presents, however, certain disadvantages. In the older cases the incision is a deep one and requires some time for healing, with great care in asepsis. As the operative measure only attacks the capsule, it is necessary that the shortened adductor and hamstring muscles should be well lengthened before incision. This is easily done in the lighter cases; but in the lighter cases reduction by incision, with the results of present experience, does not seem necessary in ordinary cases. In the severest cases the operation is not an easy one. Deepening the acetabulum by means of a curette or a Doyens instrument for the purpose is not indicated in the younger cases. It appears to have a value in adolescent cases with distorted acetabula, when the head of the femur does not fit into the socket. In the series presented one death from shock followed the operation — a double operation in an infant one and a half years old; an instance of faulty judgment in operating on both hips at once in so young a child.

TENOTOMY, MYOTOMY AND FASCIOTOMY.

Experiments upon cadavera demonstrated that in the reduction resistant structures outside of the capsule are within the easy reach of the surgeon without danger to the patient, requiring comparatively small incisions followed by traction when traction and manipulation alone are not sufficient to overcome them. The strongest group of muscles are the adductors, but these, being straight fibered muscles with but little intra-muscular septa, can be stretched sufficiently in old cases except the long tendon of the adductor magnus attached to the tubercle of the internal condyle. As this can be easily divided the chief resistance in stretching the adductor group where resistance is encountered can in this way be overcome. The hamstring muscles are accessible without difficulty to division if this is needed, and the shortened ileo tibial band and tensor vaginæ femoris; the most resistant portions of the fascia lata can be lengthened safely by a free subcutaneous incision. It would appear, therefore, that in the difficult cases it might be desirable to divide the operation into two sittings; one to overcome all resisting tissues except the capsule, and the second to open this and to effect the reduction.

STITCHING THE CAPSULE.

Various methods were employed in stitching the freed capsule around the reduced head. Handled needles, such as are used in the operation for hernia, were found the most serviceable for the purpose. Catgut was used in all cases.

FEMORAL TWIST AND OSTEOTOMY.

Femoral twists are to be found in almost all cases of congenital dislocation of the hip, as has been pointed out by Nichols. That it exists to a slight degree in normal limbs has been shown by Mikulickz and by Soutter; it constitutes, when present to an extent above 60°, a complication which may prevent a complete functional cure. Osteotomy for the correction of this complication was performed in six cases, this being done at the time of the reduction in three cases and three afterwards. Subtrochanteric osteotomy was performed in four, and in the others the operation was done at the lower end of the femur. In three instances the upper fragment was held in place by means of a steel wire sharpened like a drill and drilled through skin and bone, the ends being secured in a plaster of Paris bandage. In osteotomy at the time of the operation of reduction, fixation of the upper fragment is difficult, and it appears wiser when osteotomy is necessary that it should be deferred until the head has been well secured by cicatrization of the torn tissues in its reduced position. In performing osteotomy various instruments were used; section of the bone by a Gigli saw passed with the aid of a long straight needle to the inner and under side of the lower end of the femur between the nerves, vessels and the bone, appeared to be the most satisfactory way. It must be admitted, however, that until the ultimate functional results after reduction have been more thoroughly studied and the limit of possible correct gait with a twisted femur is better understood, it is impossible to determine the value of osteotomy in this deformity.

RESULTS.

The results of the improved method of operation by incision have proved satisfactory in an increasing number of cases as greater skill was acquired. In the earlier cases the ultimate results were unsatisfactory, but in several of the later cases perfect results with perfect motion and no limp were attained. In only one of the cases, where deepening of the acetabulum by means of a curette was done, did ankylosis follow, and in this the cartilage of the head of the femur was also injured at the time of operation. It is thought that a greater number of cures after incision would have been gained if better methods in after-treatment had been employed. Improved methods of fixation after operation have been developed in the last few years, but during this period the attention of the surgeons has been turned chiefly to development of methods of treatment without incision. It seems probable that in the future treatment by incision will be made more use of than in the past year, in the treatment of the more complicated cases.

TREATMENT OF THE IRREDUCIBLE CASES BY DISSECTION OF THE LAX CAPSULE.

This method was employed in one case, not included in the table, a girl of sixteen, and without marked benefit. The patient recovered from the operation with the limb a little lengthened but without marked improvement in gait.

SUBCUTANEOUS OSTEOTOMY WITHOUT REDUCTION.

This method has not yet been employed at the Children's Hospital.

MANIPULATIVE REDUCTION.

The manipulations employed in reduction of a congenitally dislocated hip have changed since the method was first attempted at the hospital with the Bigelow manipulation for traumatic dislocation by Dr. A. Post (at that time connected with the Children's Hospital) at the City Hospital, and the present procedure may be regarded as an entirely different one. The details of the Paci Lorenz method have been so frequently described that a further account is unnecessary, but as the anatomical relations of the parts are not as generally known, a mention of these may be of interest.

In manipulation reduction it is necessary that the dislocated head (which lies above and slightly behind the vertical plane of the acetabula) be pulled downward; as it nears the rim above the socket it is deflected, if it is not already behind the acetabulum, and must be brought forward in order to enter the socket: when it has been brought down to, though behind the level of, the middle of the acetabulum, it is not difficult, as the posterior acetabular bony rim presents in children a gap (owing to incomplete ossification), to twist the femur and push the head from its posterior position forward into the socket, provided that all contracted tissues are sufficiently stretched.

In order to diminish the resistance of the shortened tissues, viz., adductor, hamstring, psoas, and iliacus muscles, and fascia lata, the reduction is best done with the thigh flexed and abducted.

To prevent the folding in of the lower and anterior wall of the capsule as the head enters the socket, this portion of the capsule must be kept on the stretch as the head is pushed downward and forward. This manipulation is ineffectual unless the shortened muscles are stretched, and also all obstructing portions of the capsule, ligaments, and fascia lata are sufficiently stretched.

This, in manual reduction, is done by using the femur as a lever, the knee and leg as a handle, and the head as a dilating and stretching force.

It is manifest that considerable skill is required, not only to stretch contracted tissues and replace the head without folding the capsule, but also to avoid any unnecessary injury to the tissues, nerves, arteries, or bone, for the surgeon has in his hands an implement of great force.

The objection to the method of reduction by manual manipulation is that not only is there danger of injury, if skill is not employed, but even with the employment of the best skill, in certain cases the pressing of the distorted capsule into the acetabulum in front of the reduced head may take place.

This was clearly shown in a pathological specimen already described in the orthopedic section of the Warren Museum. When the capsular neck is smaller than the head and where this constriction is too resistant to be dilated, folding of the capsule into the socket necessarily follows.

In a case of congenital dislocation of the shoulder, at the Children's Hospital operated on by Dr. Brackett, it was found on cutting down to the joint that it was impossible to prevent some folding in of the capsule on reduction, and it was necessary to open the capsule and remove the fold to secure perfect apposition of the bones of the joint. In how many instances of congenital dislocation of the hip this difficulty is likely to occur, it is impossible to say at present. It was in the belief that this was a frequent complication that reduction by incision was performed at the Children's Hospital in a large number of cases; in a few it appeared from the narrowness of the capsular constriction that no complete reduction was probable without incision; in many, however, it appeared that the capsular constriction was neither so small nor so resistant as to preclude successful reduction by manipulation.

In a specimen of double congenital dislocation in a six-months' fetus in the possession of the Warren Museum, and dissected by Dr. S. Robinson, of the Anatomical Department of the Harvard Medical School, it appears that no capsular constriction is present in the early stage of the deformity. It is probable that the older and more severe the deformity the greater the capsular constriction.

It is claimed that where a folding of the capsule in front of the reduced head is present it will be

gradually worn away by the pressure of the head in the acetabulum in locomotion. Such an assumption, however, is not based upon pathological evidence. Strong, ligamentous tissues, instead of diminishing in thickness, often increase under pressure. It would seem more probable to assume that the folding in of the capsule in front of the reduced head is one of the causes of relapse, which diminish the percentage of cures in the treatment of congenital dislocation of the hip.

The frequency of relapses has been attributed to shallowness of the acetabulum, but both pathological specimens and the experience of those who have cut down on congenitally dislocated hip joints justifies the statement that shallow acetabula are by no means so common as to justify such a higher percentage of relapse. Some other cause must be sought to explain this failure. Imperfect reduction, twists of the femur and defects of the acetabulum are all mentioned, as well as the folding of the capsule in front of the head of the femur in reduction. These, however, are hardly satisfactory explanations in relapsed cases where the head has been definitely reduced into a deep socket, both after reduction by manual manipulation and also after incision where the capsule was definitely not folded in front of the head.

If the six-months' fetus with this deformity is examined it will be found that the head is connected with the socket by a stretched and loose capsule, which permits the position of the head to lie above and behind the acetabulum, or to be placed in any position permitted by the length of the relapsed capsule. The muscular and ligamentous obstructions will be found to be slight, and the acetabulum not much more shallow than that found in fetal conditions of the same age. There is, however, in the fetus afflicted with this deformity, a noticeable absence of the cotyloid ligament. Even in a four or six months' fetus it will be seen that it is the cotyloid ligament which holds the head of the femur in its proper position, and checks a dislocation. It has been claimed that the shallowness of the acetabulum in a congenitally dislocated hip joint is the usual cause of the relapse after successful reduction. An examination of pathological specimens, however, of this deformity and the experience of those who have operated upon the joints by means of open incision with a careful exploration of the acetabulum, justified an assertion that a shallowness of the acetabulum to an extent preventing the retention of the replaced head in the socket is much more rare than would account for the frequency of relapse after successful reduction. If the depth of the acetabulum in a normal child of five is examined, it will be seen that unless a proper cotyloid ligament exists holding the head in its place, dislocation would invariably occur on any extensive motion of the hip. The condition is not unlike that of the shoulder joint of an adult, where a dislocation is prevented not so much by the depth of the glenoid cavity as by the strength of the surrounding tissues. It would appear, therefore, that for successful treatment of cases of congenital dislocation of the hip after reduction, it is necessary that the capsule should fit closely and not loosely around the head.

After reduction, a suitable position for the limb, avoiding improper stretching of the capsule, would be with the center of the head of the femur in contact with the center of the acetabulum, but in the first month following reduction, it is desirable that there be no possibility of pressing the head of the femur against the part of the socket least capable of resisting pressure until the cartilaginous rim which crowns the edge of the socket has been given strength enough at the weakest part of the acetabulum to retain the reduced head. For this reason, it is desirable for a time, until muscular balance has been established, that the muscles which would adduct and press the head of the femur up be placed at a disadvantage, and it is for this reason that the so-called frog position is of service shortly after reduction; but as it is desirable that the portion of the capsule, which should be strong and compact, should not be stretched and thereby weakened, it is essential that as soon as feasible the limb be put into position as near the normal as is possible, in order that no contraction of the capsule or torn ligaments be established which will not permit the necessary free rotation of the trochanter when the limb is placed in its normal position. If these contracted tissues are strong a transposition results if the upper and forward portion of the capsule is lax. The position of the limb after reduction, therefore, must be a matter of judgment as well as the length of time it is maintained. The question is still further complicated by the twist of the femur and the alteration in the femoral neck, which is present in a large number of cases, a complication already referred to.

Investigation has shown that a considerable twist may exist in the femur within the range of normal function, but where an extreme twist is present the danger of abnormality may be said to be reached. It can be expected that the shape of the bone will, by growth, be altered, if complete reduction has been established.

It would appear, therefore, that besides a shallow acetabulum, an infolded capsule and a twisted neck, that a relapse may result from a relaxed capsule which may come from an after treatment with a faulty position, or the too long continuance in such a position as would develop a lax capsule with a faulty contraction of the ileo-femoral tissues. This might occur even if the frequent cause of relapse, a loosely fitting or imperfect plaster cast, is not present.

It is manifestly desirable that the position of the limb (with, if necessary, a change of position) be inspected frequently and that x-ray examinations be made at suitable intervals, in order to correct any tendency to transposition or to relapse. This appears more safe than to trust, without removal of the plaster and examination to the changes which may develop in the socket from use of the limb.

An attempt at the hospital has been made to substitute a removable appliance for a plaster bandage for fixation of a limb after the post-operation plaster of paris bandage has been worn for two months. This will enable the surgeon to inspect the limb with care more frequently than when a plaster bandage is worn. An appliance devised by Dr. J. Adams is on trial for this purpose.

MECHANICAL OPERATIVE STRETCHING.

In all cases of congenital hip reduction the fixation of the pelvis during manipulation is of importance. This is difficult in the older and more resistant cases, and for this reason in the severe cases some form of mechanical stretching is of assistance.

Precision in the use of the applied force is desirable. Where this can be furnished by a proper mechanism it is manifestly of great assistance. There are manifest disadvantages to the surgeon in the employment of any mechanism, but when this can be done greater efficient force can be exerted than can be expected from the hands of a surgeon, even if aided by a number of assistants.

Various mechanical devices have been used at the Children's Hospital. The latest, devised by Mr. Bartlett of Boston, is the most effective. It has been used not only in cases beyond the usual age limit, but also in younger cases of five and six, as there seemed to be less danger of injury to tissues, less ecchymosis when it was applied, than when manual manipulation was used; it is of much use in double cases. As is seen by the table, with its use children come under the class in which treatment is possible at a much older age than has hitherto appeared possible; the danger of fracture is removed, if the mechanism is used intelligently. A full description of this appliance with an explanation of its method of use will be found in the *Journal of Medical Sciences*, December, 1903.

AFTER TREATMENT.

The length of time necessary for after treatment is necessarily a matter of judgment in each case. Where the capsule is well contracted about the head and is firm, it is manifestly necessary that no longer time is needed for fixation than is required for the thorough healing of torn tissues, if a sufficiently deep socket is present. Where too lax capsule is present, or an abnormally twisted femur, it is a question of an operation shortening the capsule, an osteotomy or the retention of the limb for a year in a fixed bandage with the resulting atrophy of tissues. Practice will, it is thought, tend to the shortening rather than the lengthening of the time of after treatment by fixed bandages with operative intervention to meet the above mentioned complications.

Massage and exercises naturally suggest themselves as of use after the removal of fixed bandages to hasten the usefulness of the limb and promote the proper rotation of the limb from the abducted to the normal position, but the natural activity of the child can be expected in time to develop the normal functions of the limb provided the reduction is complete. This has been relied upon in a majority of the cases here reported; the value of systematic massage and regulated gymnastics were demonstrated in two cases, in which they were thoroughly carried out.

ADULT CASES.

A number of adult cases, eleven in all, not included in the table of this report, have applied for treatment, and thereby an opportunity given for observation of the ultimate results of neglected cases. The age ranged from sixty to sixteen. The one of sixty applied for treatment on account of calosities of the foot from an equinus position. She had enjoyed perfect health during life, had been the mother without difficulty of four children. She had several times been obliged to use crutches for periods of from six months to two years, but had recovered so that locomotion necessary to an active life was not difficult, with the occasional use of a cane. She was a large woman of active, uncomplaining temperament.

Cases of feeble strength, even if of slight figure, frequently suffer considerable temporary disability accompanied by muscular pains, considered rheumatic, which may be so severe as to require rest in bed for some time; while some cases of equal size may possess sufficient muscular strength to enable them to walk freely and without difficulty, and with little rocking in their gait. The latter is the exception, however, and the deformity, even in single cases, constitutes a disability of greater or less severity, preventing the active occupations.

In one case, a feeble girl of nineteen with double dislocation, locomotion was impossible without crutches.

Palliative treatment in these cases is of some assistance; massage, the temporary use of crutches, and in cases with severe lordosis the use of a spinal corset is of help. Operative treatment, cutting down upon the joint, deepening the acetabulum, osteotomy, may be of benefit in some of the adult cases, but was not considered in the cases here mentioned.

Forcible manipulation appeared to be of assistance in one case, though it was uncertain how much of the benefit resulted from a mental stimulus and how much to a positive improvement.

As a rule, the condition after treatment, if only partially successful, was better than the usual condition in neglected cases, if the latter are examined in adult life. In childhood, however, the deformity occasions so little disability or discomfort that suitable treatment is often regarded as unnecessary.

In the cases here presented there were but 20 males in the 144 cases. In two the deformity occurred in another member of the family, in one in an older, and in the other in a younger, sister. Of those cut down upon, in one, the head of the

femur was entirely absent; a twist of the femur appeared to be present in a large proportion of the cases; flattening of the head and lowering of the axis of neck occurred in all the older cases, ten or older. Fifteen of the series presented double dislocation.

RESULTS.

The results presented indicate a gratifying continued improvement in treatment from the period when all attempts were fruitless even among younger children. At present, even at an increased age, the percentage of cures is considerable.

It appears to be safe to claim that for all cases, single and double, under ten years of age, either by manipulation by the use of mechanical force, or by reduction by means of incision, a complete reduction is possible, and that relapse can be prevented in more than 60% of the cases. For this, however, careful attention should be paid to after treatment with attention to the following details. It is believed by the writers that a higher percentage and at a higher age limit can be expected, if all methods, including the operative in the more difficult cases, are employed. *First*, that the position of the limb should be such that the development of a firm cotyloid ligament be favored. *Second*, that the position of the limb should be such that the capsule should not be unduly stretched in its forward portion. *Third*, that the position of the limb should be frequently inspected and x-ray examinations be made at frequent intervals.

Double cases are found to present more than twice the difficulty of single ones, and may require repeated operations to secure equally good results on both sides. Although operation by incision without and with curettage of the acetabulum in the complicated cases will be used, in all probability, more commonly than at present in the cases when the simpler methods have failed. The method by forcible manipulation is, in the opinion of the writers, the one to be employed in the usual cases.

From the experience gained at the Children's Hospital it appears also to the writers of this report that stretching the tissues by an efficient machine gives in resistant cases an unquestioned advantage, and permits better reduction, with less risks and in older patients, than if operative manipulation alone is employed.

There is a certain analogy between the treatment of congenital dislocation of the hip and that of club foot. In the simpler cases, manipulation under an anesthetic is sufficient. In the more resistant cases, correction is helped by mechanical aids; in the oldest and complicated cases, incision and osteotomy are often needed to perfect the cure.

The present condition of the treatment of congenital dislocation of the hip may seem to illustrate that the world advances by impossibilities achieved. Twenty years ago, cure of this deformity was considered impossible. This in many cases is now easily accomplished.

CASES OF CONGENITAL DISLOCATION OF THE HIP OPERATED ON AT THE CHILDREN'S HOSPITAL FROM 1884 TO 1896.

By mechanical appliances without operation:

	Date	Age	Sex	Hip	Remarks
1.	Feb. 25, 1884	3	f	not men'd	
2.	Sept. 20, 1887,	6	f	left	
3.	Nov. 3, 1888,	2 5/12	f	double	
4.	Aug. 26, 1889,	9	f	right

II.

ADDENDUM.

BY E. H. BRADFORD, M.D.

RECOGNIZING the difficulty of determining with definiteness an absolute cure in many of the treated cases of congenital dislocation of the hip, the staff of the hospital collected a number of children who had been treated in the previous two years and demonstrated their conditions with their skiagraphic record at a special meeting of the Boston Society of Medical Improvement, which was held at the Children's Hospital and to which the leading physicians and surgeons of the city were invited. A committee of three was appointed by the president of the Society for Medical Improvement to examine personally the cases shown and report upon their condition. It was stipulated that the committee appointed should be made up of surgeons not connected with the Children's Hospital. The committee was composed of Dr. D. W. Cheever, Emeritus Professor of Surgery, Harvard Medical School; Dr. C. B. Porter, Professor of Clinical Surgery, Harvard Medical School; Dr. C. F. Painter, Professor of Orthopedic Surgery, Tufts Medical School and Orthopedic Surgeon to the Carney Hospital, who submit the accompanying report.

To prevent undue publicity the names of the children operated upon are not given in the published hospital report; these were, however, furnished to the members of the committee and the results of their examination are given in the accompanying committee's report. This report differs from the hospital report in two cases which were regarded by the committee as having slipped into an anterior position since their examination at the hospital.

In a majority of cases in the hospital table a sufficient time had elapsed since the removal of the plaster to justify an opinion as to the probability of a permanent cure, but in some of those examined by the committee the plaster bandage had been removed only a short time.

It is desirable to examine the effect of growth upon cases of congenital hip for some years after successful treatment and after the so-called functional cure with anterior transposition of the head, and it is proposed to re-examine in a year from the present date as many as possible of the cases included in the hospital tables.

Accompanying this paper is presented the photograph of a patient photographed when four

years of age and later when twenty-six. No treatment was attempted and the case may be considered as showing the effect of growth upon the figure. The patient was able to walk about freely and with but little side sway, and suffered little inconvenience except that occasioned by the shortness of stature. The patient was slight in figure. Another photograph submitted indicates a similar untreated case, nineteen years of age, resulting in great disability, the patient being unable to walk without crutches. One of the cases operated upon by Professor Lorenz (No. 11 of the table), and reported as resulting in a transposition, was anesthetized six months later and the limb put in an improved position. It is believed that an anatomical reduction and a permanent cure has resulted, from a statement which has been received in writing; but as the case had not been personally examined at the time of writing the report, the rule was followed adopted for all cases; viz., that the statement in the hospital records is to be published unless corrected by later examination.

It has been thought inexpedient to publish all the skiagrams of the cases in this report, some sixty in number, but illustrative skiagrams are presented to indicate the standard of results as classified by the committee.

III.

REPORT OF THE COMMITTEE OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

BY DAVID W. CHEEVER, M.D.; C. B. PORTER, M.D.; CHARLES F. PAINTER, M.D., BOSTON.

THE committee appointed at a special meeting of the Boston Society for Medical Improvement held Jan. 7, 1904, to consider the report of the staff of the Children's Hospital upon the cases of congenital dislocation of the hip treated at that institution, submit the following statement:

The cases, the subject of this report, are those operated upon during the eighteen months just preceding the date of this meeting, which have been operated on long enough to justify the removal of retentive dressings, and which were present for the examination of the committee.

These cases were examined individually and separately by at least two members of your committee, and subsequently the evidence of reduction as afforded by x-ray examinations was submitted for separate study. The examination of the x-rays was made independently of the results of the clinical examinations previously recorded, so as to render the report, as far as possible, an unbiased one.

Twenty-two cases were submitted to us for examination. Of these, one was not seen by any of the committee, and it is their opinion that the x-ray evidence was not sufficient to establish a diagnosis of the position of the femoral head. We thus have 21 cases. Ten were apparently reduced, the head being felt in the normal position, and the function of the limb, as evidenced by passive motion, being good; 9 cases were not reduced, the head of the bone being beneath the anterior superior spine and external to the femoral vessels. In these the passive motion was not as good. Two were still posterior dislocations upon the dorsum of the ilium. The active motion of the 21 cases is not reported, because it did not seem proper at this time to enter into that feature of the results.

In studying these cases your committee has laid most stress upon the results of the physical examination and comparatively little upon the x-ray findings. In some cases the x-rays submitted were taken through the plaster dressings, with the legs in the "frog" position, in which they were left after the attempted reduction. Obviously, this was not to be the position when function was restored, and it might readily be that when this abnormal position was overcome the head would no longer seem to be in the acetabulum. In the one case clinically examined by only one of the committee, his physical examination placed the case among the "reduced" list, whereas the interpretation of the x-ray would seem to negative this opinion. The case is classified, however, among the "reduced" ones.

RESULTS AS REPORTED BY THE COMMITTEE OF THE SOCIETY FOR MEDICAL IMPROVEMENT.

A METEOROLOGICAL STUDY OF THE WINTER OF 1903–04.*

BY CARROLL E. EDSON, A.M., M.D., DENVER, COL.

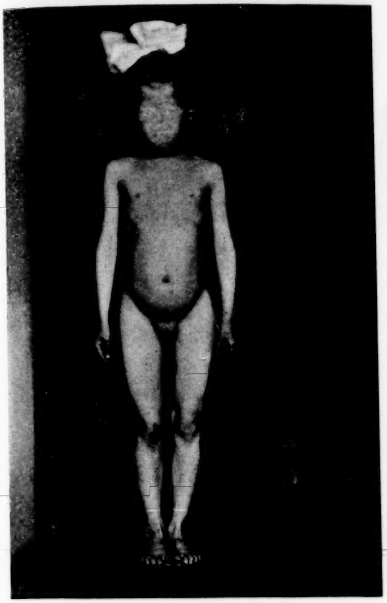
THE winter of 1903–04 was an interesting one from the standpoint of its weather, and some of its meteorological data teach a lesson of sufficient value, I believe, to present to the society.

The collation and comparison of meteorologic statistics involve frequently a kind and amount of labor for which many persons have no inclination, but the results of such study may be tabulated or reduced to graphic form so as to make easy the lesson hidden in the reports of the Weather Bureau.

I have been led to write this paper for two reasons:

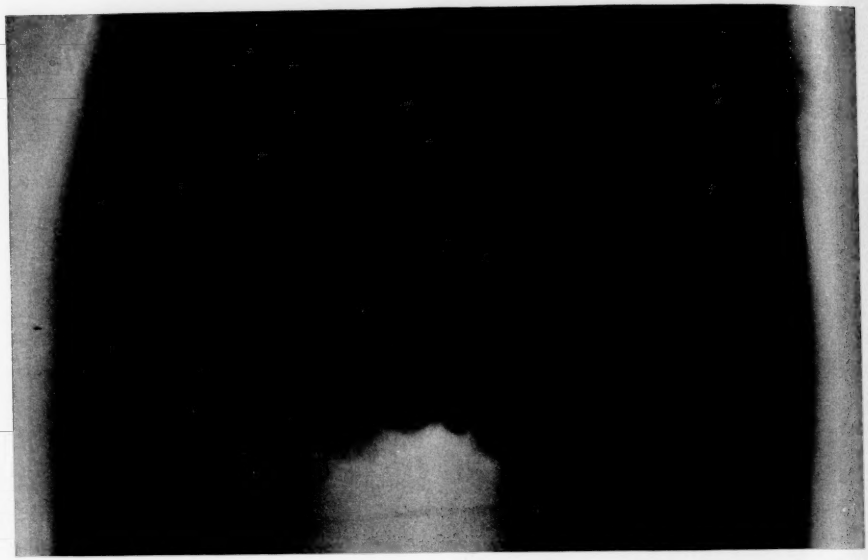
First. — The winter has been sufficiently pro-

* Read at the meeting of The American Climatological Association, Philadelphia, June 2–4, 1904.

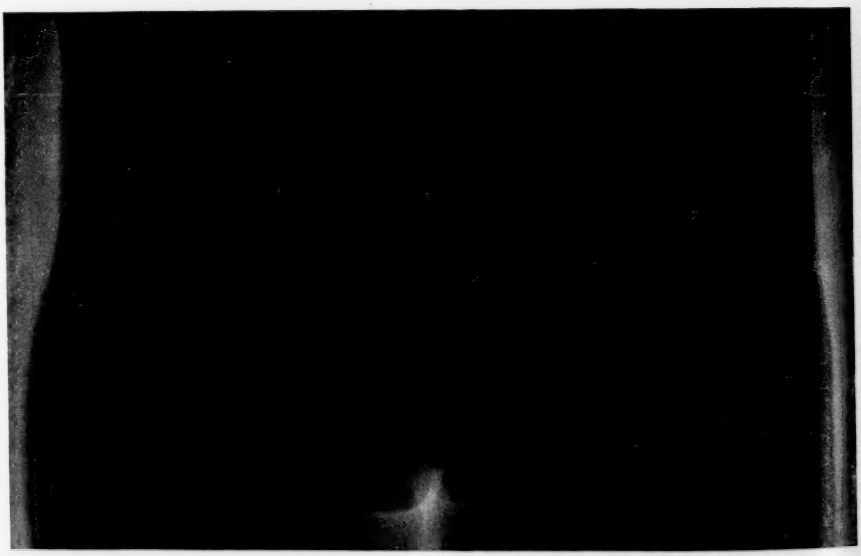


S. 6½ years old. Congenital dislocation left hip. One year after reduction by operative mechanical stretching and manipulation.

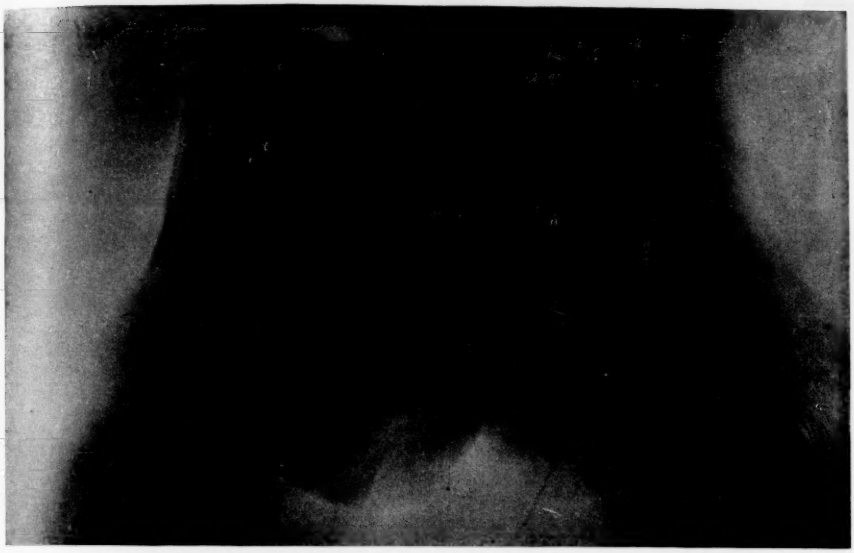
S. Showing strength of reduced hip by the Trendelenburg test. Motion and gait of reduced hip normal.



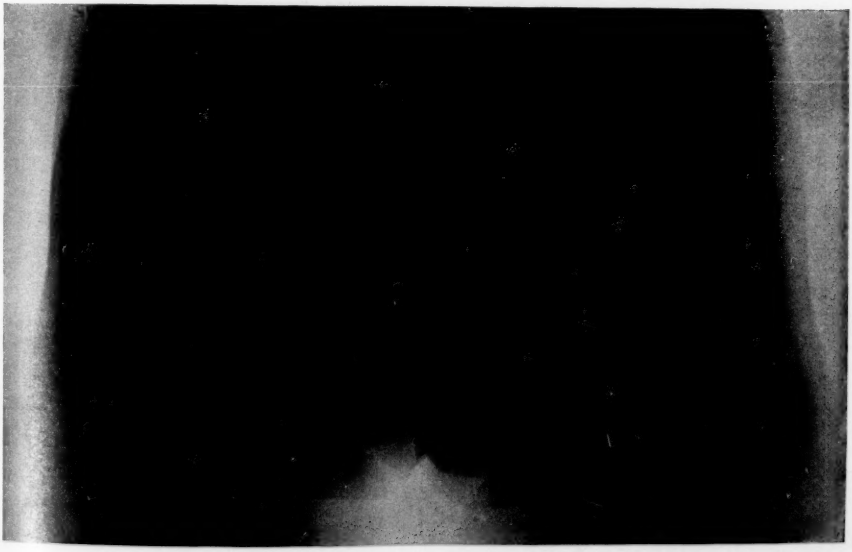
S. Skiagram one year after reduction.



T. Child of five. Skiagram taken two years after reduction by incision. Right congenital dislocation of hip. Motion and gait normal.

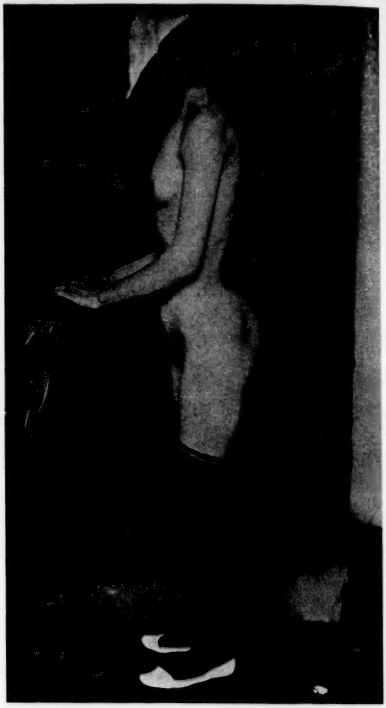


F. Double congenital dislocation, child of three. Skiagram taken three months after reduction by incision.

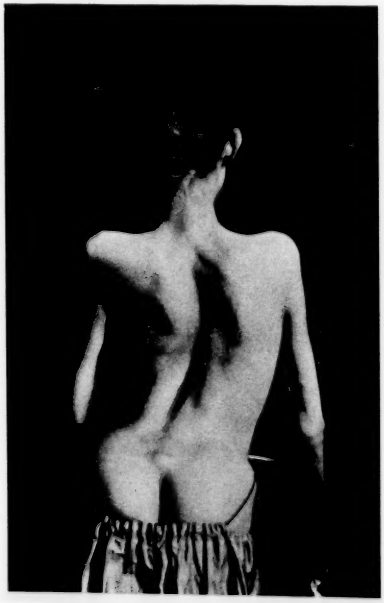


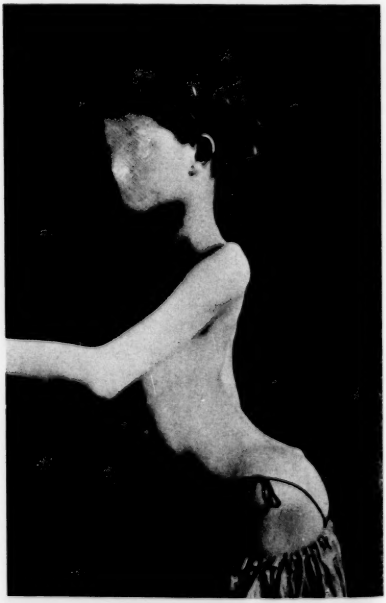
F. Same case. Skiagram taken six months later, showing anterior transposition of heads of femur.

D. Double congenital dislocation of hip. Child age four. Untreated.



D. Same patient age 28. Untreated case. Patient able to walk actively with little limp.





H. Untreated case double congenital dislocation. Unable to walk without crutches.

nounced in some of its characteristics, especially in the East, to attract the attention of those, even, whose work does not ordinarily lead to study of meteorologic conditions. To compare the recorded statistics of such a winter with the data of the mean weather conditions as meteorologically expressed, emphasizes better than any other way what must be read into these reports as published in climatic works, in order to obtain the clear picture of the actual weather of a given place. To learn what the actual figures of such a winter as the past are, gives the student a live measure for his general use.

Second. — The comparative study of the weather in various parts of the country during this winter teaches a lesson of great therapeutic value, to which I wish to call your attention.

I have selected for this study only the period of the winter — from Nov. 1, 1903, to April 1, 1904 — a period of five months or 152 days, and have taken the six cities of Boston, New York, Philadelphia, Buffalo, Chicago and Denver.

The nearness to each other of New York and Philadelphia makes their meteorologic conditions very similar, but the detailed data show some interesting differences.

My statistics are taken from the monthly reports of the United States Weather Bureau and are, therefore, comparable, being taken accurately under similar conditions of observation and time. So far, therefore, as material is concerned, I have nothing new to offer, but wish simply to point out what is already contained in apparently uninteresting columns of figures. As far as possible, I have reduced my findings to a graphic form, as being time-saving and most demonstrative of the relative conditions in the several cities. The tables on which these diagrams are based and which accompany the paper, I will refrain from reading.

Temperature. — The mean temperature of the several months and the mean temperature of the corresponding month for the period of the last thirty-three years, are shown in Table A.

Table B gives the average daily excess or deficiency of temperature over the mean of thirty-three years.

TABLE B. — AVERAGE DAILY EXCESS (+) OR DEFICIENCY (—) OF TEMPERATURE OVER MEAN OF 33 YEARS.

	Boston.	New York.	Philadelphia.	Buffalo.	Chicago.	Denver.
Nov.	—1.0	—2.4	—2.3	—1.0	—2.4	+1.8
Dec.	—2.0	—4.0	—3.8	—4.0	—8.9	+3.9
Jan.	—5.8	—6.2	—6.1	—6.0	—6.0	+1.8
Feb.	—5.5	—6.0	—5.8	—7.0	—8.5	+8.3
Mar.	+0.2	—1.2	—0.2	+1.0	+0.7	+3.6

It will be seen that Boston had a daily average lower temperature than normal of from 1° to 5.8°, save in March, when it was a small fraction, 0.2°, over the mean. New York was below, all the time, from 1.2° to 6.2° daily; Philadelphia, from 0.2° to 6.1° colder; Buffalo, from 1° to 7°, save in March, when it was 1° above the average. Chicago, also, was a fraction above the mean in March, but showed, till then, a daily average deficiency of from 2.4° to 8.9°. Denver, on the other hand, experienced a winter steadily warmer than usual by a daily average of from 1.8° to 8.3°.

The table (C) which follows shows the mean maximum and mean minimum temperatures and the actual highest and lowest. A study of these tables shows the general range of the thermometer.

It will be seen that the winter set in early in Boston, New York, Philadelphia, Buffalo and Chicago, continued late, and was colder than usual. Calculating the number of days in each month on which the temperature was above or below the mean of the months, I found that the low mean of the months was not the result of a few excessively cold days, as sometimes occurs, but that the whole winter, in the East, was steadily colder than usual. In Denver, it was, throughout, warmer.

Going a little into detail, Table D gives the number of days on which the maximum temperature was at freezing or below 32°.

The maximum temperatures are the most important to the physician, as the minimum tem-

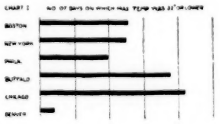
peratures occur at night, when his patient is in bed and but little affected by them, while the maximum temperature determines, to a considerable degree, the length and comfort of the invalid's out-door stay.

TABLE D. — NUMBER OF DAYS WITH MAXIMUM TEMPERATURE 32° OR LOWER.

	BOSTON.	NEW YORK.	PHILADELPHIA.	BUFFALO.	CHICAGO.	DENVER.
Nov.	5	5	4	9	10	2
Dec.	11	9	7	16	21	2
Jan.	18	17	15	20	24	4
Feb.	17	17	11	20	20	0
Mar.	4	2	2	9	7	0
Tot'l,	55	50	39	74	82	8

From the table it will be seen that, of the 152 days studied, Boston had 55 more than one third below freezing all day; New York had 50, or nearly one third of them all, below freezing; Philadelphia 39, about one fourth; Buffalo 74, or nearly one half; Chicago 82, over one half; and Denver but 8, or only one nineteenth.

This relative number of cold days is most clearly appreciated in Chart I.



Of the days when the maximum temperature was 20° or lower, Boston had 9; New York 9; Philadelphia 6; Buffalo 26; Chicago 30; Denver none.

Boston had two days below 10° all day; Buffalo 7; Chicago 7.

Buffalo had one day with a maximum of zero, and Chicago one day with a maximum below zero.

These few days of very low temperature, while showing an unusual freedom from "cold waves," emphasize the conclusion stated above, — that the great deficiency in the mean temperature was due to continuous, steady cold all winter, and not to intermittent spells of excessive cold. There is an importance in this for the out-door life of an invalid. With a low mean temperature, he may still be out much of the time, if the mean is the result of a few excessive cold periods, for, during such cold days, the temporary housing necessitated is of comparatively little harm, while if the low mean is the result of a continuous cold, it may cause a sensitive patient to lose a large portion of his needed out-door stay.

Chart II, showing the mean temperature by months, with the comparative range of the mean maximum and mean minimum readings, discloses the fact that during January the mean minimum temperature in Denver was above the mean of Buffalo and Chicago, and in February higher than the mean maximum of those cities. In other words, in February it was warmer in the coldest part of the night in Denver than it was in the warmest part of the day in Buffalo or Chicago.

Relative Humidity. — Closely associated with the temperature of the air in affecting the comfort is the humidity, the discomfort of both extremes, heat or cold, being increased by a high relative humidity.

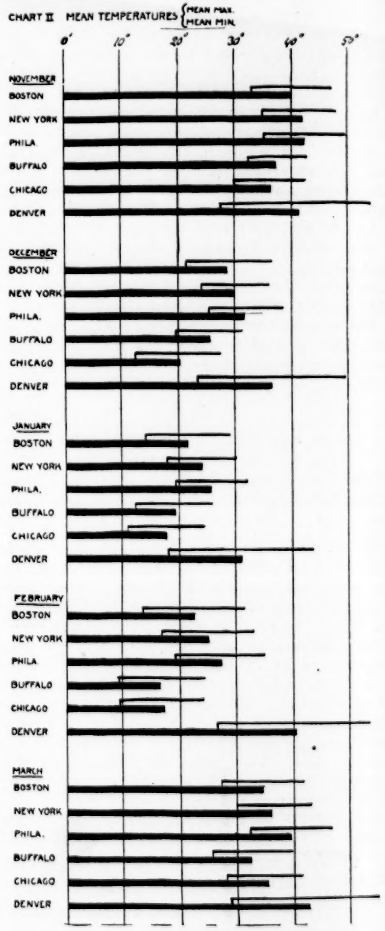


Table E gives the mean relative humidity in the several cities, at morning and night.

Starting with the humidity of the early morning, before the air is warmed by the sun, the relative higher or lower figures at night give some index as to the degree of rawness during the day. If the amount of moisture, actual, remains the same, as the air warms the relative humidity will fall. Accordingly, if the relative humidity rises as the day goes on (and the air is warmed) and is higher at night, there has been an actual increase

in the amount of moisture or else a fall in the temperature during the day. In either case, cold and chilly rawness has been a feature of the day.

Studying Table E with this in view, it will be seen that there is a comparatively small drop in the relative humidity at night in most of the

Of the 152 days studied, Boston had 55 wholly cloudy days; New York 58; Philadelphia 58; Buffalo 112; Chicago 66; and Denver 14.

Of fully clear days, Boston had 67; New York 65; Philadelphia 59; Buffalo only 9; Chicago 31; and Denver 71.

lines, and that often there is an actual rise. The extremely high humidity in both Chicago and Buffalo, and the frequent higher night humidity in the latter city, are to be noted. Boston showed an average higher humidity in the morning over the evening of 4°, New York of 8°, save in January, when the humidity was higher at night by 2.9°; Philadelphia of 7°, Chicago of 8°, Denver of 11°; while Buffalo has the damp, chilly record of being higher at night in December, January and February — the cold months — by an average of 1.7°; and in November and March a morning higher humidity of 3.7°, or averaging for the whole winter a higher morning humidity of only 0.4°.

Sunshine. — The total number of hours of actual sunshine and the percentage of the total possible are given in Table F for the winter and by months; and the percentage for the whole period is shown in Chart III.

Table F. — Sunshine, Nov., 1903, to April, 1904.

Not only the total percentage of sunshine, but its distribution, is of importance in studying the relative availability of out-door life. For the effect of sunshine and cloud is not only that upon the temperature and moisture, but a positive one upon the mental well-being of a patient.

The study of the proportion of sunshine and cloud for the last winter is interesting.

Table G shows the number of wholly cloudy, partly cloudy and clear days in each month, and the total number of days on which 0.01 of an inch of precipitation fell.

For continued pall of cloud, Buffalo holds the record; out of 152 days, only 9 sunny days.

Chart IV shows the relative number of days of cloudy, partly cloudy and clear weather.

The depressing effect of continued cloudy weather, without any sunshine, is very great, and in winter, especially, long absence of sunshine greatly hinders out-door life. A study, therefore, of the distribution and duration of the wholly cloudy days becomes of some interest.

I have reckoned the number of times there was a period of total cloudiness of three consecutive days, and find that Boston had 2 periods of four days, 4 of three days and, in addition, 9 periods of two days; New York had 2 periods of five days, 1 of four days, 1 of three days and 10 of two days; Philadelphia had 1 period of five days, 2 of four, 4 of three and also 7 of two days; Buffalo had the unenviable record of 1 period of twelve consecutive wholly cloudy days,

1 of eleven, 1 of eight, 3 of seven, 2 of six, 3 of five, 2 of four, 4 of three and also 3 of two days; Chicago had 2 of six days, 1 of five, 1 of four, 3 of three and 8 of two days; Denver had no period of two days, even, of consecutive total cloudiness.

None of the periods above stated are included in any other, and they are all apart from partly cloudy days, being each of them a series of consecutive totally cloudy days.

Precipitation. — The past winter has been one of marked snowfall throughout the East, the general impression being of an unusual amount. On studying the records, however, it will be found that the precipitation was in general below the mean of the last thirty-four years. Table H gives the precipitation by months, and in small figures in a parallel column the mean for that month.

side by side, each feature compared with the other, if we are to obtain a true picture of the conditions actually present. To read the totals of any column alone will almost necessarily give a wrong idea, even of that factor, but there must be juxtaposition and constant reference; the sunshine, the temperature, the precipitation, must be read together, if they are to mean anything, and give a clear picture of the actual conditions.

Wind. — The total wind movement each month is shown in Table K, and in the small column the highest velocity during any five-minute record.

It will be more easily appreciated by reducing the total wind movement to a proportion in smaller figures, which gives Boston 84, New York 115, Philadelphia 79, Buffalo 128, Chicago 127, Denver 66, as shown in Chart VI.

It will be seen that Buffalo alone had more than the usual precipitation. Chart V makes the comparison easy, the small perpendicular lines addressed by an arrow indicating the point of mean precipitation beyond that of this winter.

That a less precipitation than usual should give rise to a general impression of an excess is due to the fact that, owing to the cold weather, the low temperature, the precipitation was as snow rather than rain, and, owing to the persistent low temperature, this snow did not melt as usual from time to time in periods of thaw, but remained on the ground as snow and ice, encumbering the streets and making progress difficult. A slight difference in the mean temperature would have made a great difference in the impression of the winter.

No better instance could be selected to show the importance of studying meteorological data

In reading the tables, too, it must be remembered that the air is lighter at Denver than in any of the seaboard or low level cities.

The winter just passed may be described, then, as regards Boston, New York, Philadelphia, Buffalo and Chicago, as setting in earlier than usual, lasting longer and being somewhat colder than the mean, this coldness, however, being due not to the depressing effect of cold waves so much as to a continuous, steady cold, without much let-up. For this reason the precipitation though less than usual, save in Buffalo, was more noticeable, coming as snow and remaining frozen on the ground. The cloudiness, especially in Buffalo, was extreme.

In Denver, on the other hand, the winter was one of unusual mildness, small precipitation, very even temperature and abundant sunny clear days.

The therapeutic lesson to which I wish to call attention by the foregoing meteorologic study is that of the importance and advantage of selecting the climate in the care of pulmonary tuberculosis.

The present position of appreciation of the importance of fresh air, sunshine and nutrition in the treatment of phthisis has been slowly attained. The progress from drugs and palliation to the insistence on control of the simple, hygienic living, has been by stages. As in all lines of human thought, so in therapy, the tendency has been to see but one point at a time, — to lay stress on one factor to the neglect of others. In the general advance of our knowledge of phthisis and its care, one stage was marked by the great emphasis laid on climate, and we heard only of the climatic treatment, as distinct from the medical, as if climate was in itself an entity and a specific force.

A frequent result of this narrowness and separation of ideas was that patients were sent away for a "change of climate" to a supposedly "proper climate" away from home and allowed to shift for themselves, neglecting all details of control and hygienic living, placing such matters in the intelligent care of the climate. Much evil resulted from this course, as might have been expected. Many and marvelous cures were often made. Of the untold failures, many might have been avoided.

Gradually, as the appreciation of the need for close oversight and control of the patient became more keen, it was found that the discipline of a sanatorium was of great help. Patients were noted to recover their health at home with their own native "weather," without the aid of "climate," once more investing climate with an air of specific entity.

Then we heard for a while of "the sanatorium treatment" as distinct from the medicinal or the climatic, — another stage in our advance, but still marked by the old "one idea" tendency. The advantage which this sanatorium control brought about by its close oversight of all the details of life, food, outdoor exercise and so on, was seen in the cures resulting in many "closed institutions." Our present better knowledge of the disease and its proper management by control of all details of hygienic living out of doors is due, in part, to such study as was more possible in an institution.

As a result, there has been lately considerable remark by various writers that "climatic stations" are of no great importance; that food, sunlight and fresh air are all that are needed. "Out of doors is all — anywhere is good enough." Again the old tendency to see but one thing at a time! But is it true?

Granted that the important factors, as we now know them, in the care of pulmonary tuberculosis are, after control of the patient and his living, food, fresh air, sunshine, an outdoor life — are these latter helps the same everywhere? By no means, and even the brief comparison of the winter just made must prove that some places offer more opportunity to the invalid to live comfortably out of doors than do others.

Leaving, for the present, wholly out of question any especial advantage of high elevation upon the patient or his disease,— taking only the elements of the weather as just discussed,— is there no choice? If the patient is to have the closest control, the most nutritious food in the greatest abundance, the most carefully regulated exercise and a constant life in the open air, ought he not to be given the greatest opportunity to lead that life? Fresh air is fresh air; sunlight is sunlight. The air in Buffalo, for instance, was probably just as fresh as in Denver and the same sun illumed it, but was that fresh air as available to the patient? In the one city, out of 152 days, 112 totally cloudy; in the other, 18.

Or could a patient, ordered to keep quiet, spend as many hours out of doors with a mean temperature of 18° in Chicago, as in Denver, where the mean minimum was much of the time higher than the maximum in Chicago?

Climate is not a thing in itself; it is only the conditions of sun and rain and heat and cold and wind prevailing in any place. It is not a treatment for anything, but in a disease in which our weapons are discipline, food and outdoor life, a study of meteorologic conditions will enable us to place the patient where he can obtain the best opportunity for living that outdoor life most constantly and most comfortably.

It is not necessary to press individual comparison further. I have said enough to show that a study of such tables as I have given in this paper will prove that all weather is not the same, that all fresh air is not equally good, and that a location like that of Denver does offer, by the conditions of its climate, its lack of storm, its absence of cloud, its warmer sunshine, definite advantages for the outdoor life so essential to the welfare of the tubercular invalid.

IMPLANTATIONS OF SILVER FILIGREE FOR CURE OF LARGE VENTRAL HERNIA. REPORT OF TWO CASES.*

BY H. B. PERRY, M.D., NORTHAMPTON, MASS.

THERE is no operation of reconstruction that the surgeon is called upon to perform that taxes more the resources at hand or promises less as far as restoration of function is concerned than large, ventral hernia of long standing, whether post-operative, congenital or acquired. The principle involved in the two cases I have the honor to detail to this society is an old one, although the technique is of a later period than when silver wire was first used as a buried suture.

In the evolution of suture materials silver wire has always been in evidence. Shede was the first to use it as a buried suture. His method was to include all the structures except the skin as a preventive of subsequent hernia. A new impetus was given the silver wire suture when

* Read before The Massachusetts Medical Society, June 7, 1904

Credé published his discovery of the antiseptic properties of silver. In this country A. M. Phelps of New York was one of the first to use silver wire sutures in closing abdominal wounds, as well as its use in radical cure of hernia. The plan followed by him was to use a single strand, crossing and recrossing, to insure strength and solidity. The cases done by him were not, in the main, successful, owing, no doubt, partly, to faulty asepsis, partly to the impossibility of using a single strand of wire without more or less strangulation of the tissues and, consequently, tissue necrosis. His use of silver wire began in 1892. From this time until 1900, when O. Witzel of Bonn published a report of a series of cases of hernia, giving results of the use of buried silver wire, very little progress was made, and the advance made since then is largely due to improved asepsis. Witzel's plan was to form a weave or network over the hernial opening with a single strand of wire. About the same time that Witzel reported his cases, R. Gopel of Leipsic reported a series of cases wherein a previously prepared silver filigree pad was sewed over the opening in the abdominal wall. This was the first account of the implantation of a silver filigree pad being used to cure large, ventral hernia. His deduction from his cases and claims of superiority for this particular method over that of Witzel's are as follows:

First: The tissues bordering the hernial opening are less exposed to injury and constriction.

Second: The time for operation is reduced.

Third: The meshes with the ready-made wire pad are of equal and regular dimensions, and diastasis, even of small size, less frequently met with.

Fourth: The amount of silver wire left is reduced to a minimum.

In November, 1902, Dr. Willy Myer of New York reported, in the "*Annals of Surgery*," three cases. In two of his cases previous attempts at repair had been made and were failures. The third case, owing to a large amount of adipose, seemed hopeless, except some means out of the usual line were attempted. His reports of the three cases were eminently satisfactory. The technique, as described by him, is the one employed in the cases to be reported.

It will not be necessary for me to consume time by giving in detail all of the steps of the operation, but to say that it is identical as though autoplastic repair were to be done, up to the point of closing the hernial opening. From that time the plan of procedure is as follows: The omentum should, if possible, be stitched to the margin of the hernial ring. The sac is cut away, except that sufficient is left to close over without much tension. This is done with a continuous silk suture. The fat is then excavated sufficiently wide to admit the silver wire pad and permit stitching its border to the muscles and fascia. This is done with a continuous silver wire suture of sufficient length to have its starting and finishing points together, thus reducing the rough points left to the minimum. This completed, the skin and fat is closed over all by interrupted silkworm-gut sutures. The silver pad should be of sufficient size to overlap the margins of the opening from one half to one inch. This plan is permissible only and indicated only in the classes of cases where autoplastic repair is impossible with any assurance of success, for any or all of the following reasons:

First, the large size of the hernial opening; second, long existing hernia; third, atrophy through pressure and fatty degeneration of the adjacent muscular and fibrous tissues; fourth, and most frequently, previous unsuccessful attempts at autoplastic repair; and fifth, in fatty abdominal walls.

The following cases are illustrative of two distinct types, the first a post-operative hernia having had an attempt at repair, the second an acquired umbilical hernia of many years' standing.

CASE I. Mrs. A., age fifty-two, occupation housekeeper in a factory boarding-house. In 1890 this woman was operated upon and a large ovarian cyst removed. A year later, as a consequence of vomiting violently after ether to reduce a Colles' fracture, a hernia in the ventral scar developed. A year after that an operation for the cure of the hernia was done, which was unsuccessful, inasmuch as in six months the hernia returned as bad as before. This woman felt after the first trial that a cure was impossible and began a truss and abdominal band existence. In 1896 matters grew worse, and until 1903 she had been a constant sufferer and from 1900 she had never had a day free from pain, many times requiring large doses of morphine to be comfortable. In January, 1903, she was a woman five feet two inches in height, weighed one hundred and ninety pounds, with a fat, pendulous abdomen. The hernia was very large, containing intestine and omentum, and was not reducible. On Jan. 16, 1903, she was operated upon and a silver filigree pad, four by six inches, was stitched snugly to the muscles and fascia, around an opening two inches and a half wide and four inches in its longest dimension. In this case we could not utilize the omentum by fastening it to the margin of the hernial ring, because at this and at previous operations it had been very largely removed. The skin was sutured over the pad by interrupted silkworm gut. In ten days the wound had healed entirely, she was allowed out of bed in three weeks and went home in four.

CASE II. Mrs. B., age forty-three, occupation housewife, had had a hernia for a long time, could not remember when it began, but for the last six years it had given constantly increasing discomfort and pain, until, the 1st of March, 1903, life had become unbearable and the patient sought and accepted anything that offered any chance of relief. This case was first seen the 12th of March, 1903. She was then a woman five feet in height and weighed about two hundred pounds, with a large deposit of adipose over the abdomen. The hernia was a little to the left of the umbilicus and contained mostly omentum and was not reducible. Her operation was done March 20, 1903. The hernial opening was two by two and a half inches, the largest diameter in the direction of the long axis of the body. In this case the omentum was stitched to the margins of the openings with a continuous silk suture, and a silver filigree wire pad, three inches by

four inches, stitched to the muscles and fascia with a continuous silver wire suture. The skin was closed by interrupted silkworm gut with the usual dressings. This patient was out of bed in three weeks and was allowed home in four.

In each case there were indications for this operation; namely, each of long standing, with atrophy and thinning of the muscles and fascia, large hernial openings and, in Case I, previous attempts at repair. These cases have been seen recently and are well. Case I, eighteen months after operation, is, with the assistance of a green Polish girl, caring for a large family. Case II, fifteen months after operation, is doing the housework for herself and husband with comfort, which she had been unable to do for several years before. A close examination of each case shows a firm, solid abdominal wall without suggestion of diastasis. These women claim to experience no discomfort or consciousness of a foreign body in the abdominal wall, and are both enjoying life thoroughly. The question naturally arises, Will they ever experience any trouble, and, if so, why, after more than a year of freedom? The operation is not difficult, and, with strict asepsis, should be successful.

I venture to suggest this operation as a remedial agent worthy of the trial in that class of cases where tissues already existing in the patient cannot be utilized to cure the defect.

Clinical Department.

A CASE OF MALIGNANT ENDOCARDITIS WITH RECOVERY.

BY CHARLES F. WITHINGTON, M.D., BOSTON,
Visiting Physician, Boston City Hospital.

The following case, interesting from the etiology and as bearing upon the disputed question whether cases of this very grave disease ever recover, seems deserving of record.

The patient, a male, single, aged twenty-six, entered the City Hospital April 19, 1904. He had been usually healthy, but had had an attack of gonorrhea, his first, about March 8 of this year. Two weeks later he came down with measles, and two days after he began to sit up. Following this disease, he was taken with sudden and severe pain in the region of the heart, with dyspnea, lasting severely for four hours. There were chills and irregular fever with sweating and cough, which have persisted during the intervening time till his admission to the hospital. Four days before entrance he had pain in his left leg, which rapidly swelled and turned purple; sweating increased.

The physical examination on entrance showed a well-developed, but very sick-looking man. Temperature, 102–103; pulse, 160–170; orthopnea. The heart area as shown by percussion was 3 cm. to right and 16 cm. to left of the median line; a thrill, presystolic in time, was felt below the nipple; gallop rhythm; no murmur was heard at the apex, but a short systolic was heard in the fourth space to the left of the sternum. There were limited areas of consolidation in both backs, toward the bases, not involving the whole of either lower lobe. There was marked phlebitis of the left leg throughout its whole extent. The left calf measured three inches more than its fellow, and the thigh was only a little less swollen. Marked tenderness over the popliteal and femoral veins. Leucocytosis, 16,200.

During the next few days the heart action grew less tumultuous, the murmur became more distinct. Pulmonic second increased; no pericardial friction. The fever ran from 103 to 101, but showed a tendency to lowering of the curve. On April 25, six days after entrance, and about thirty-eight days after the onset of the gonorrhea, blood was taken from the vein at the elbow with antiseptic precautions and was reported by the pathologist of the hospital to show in the culture gonococci. This confirmed the opinion already held that the endocardial trouble was of gonorrheal origin. Soon after this the fever curve reached normal, and after April 28 the temperature never again rose much above the normal line. The phlebitis was distinctly less on April 30.

May 8 he began to sit in a wheel chair. The systolic murmur is still present, as before, but there are no cardiac symptoms, and the heart area is less than before. There is no dyspnea. On May 19 the limits of heart dullness were 2.5 cm. to right and 11 to left of the median line. A white count on May 28 showed 9,400 leucocytes.

In early June the patient was practically well, walking about and having no symptoms. The murmur is still heard, loudest in the second left interspace, less distinctly at the apex. The areas of consolidation in the back, which were considered to be pulmonary infarcts or embolic pneumonia, were nearly resolved.

Of course, the rôle of gonorrhea in the production of some cases of ulcerative endocarditis is now established by numerous post-mortem observations, but I believe few cases have occurred in which pathologists have been able to demonstrate this organism *intra vitam* in the blood current.

Medical Progress.

RECENT PROGRESS IN NEUROLOGY.

BY PHILIP COOMBS KNAPP, A.M., M.D., BOSTON.

PLANTAR REFLEX.

Barnes[1] has examined the plantar reflex in about 2,500 cases, fifty per cent of whom were suffering from organic nervous disease and twenty per cent from "functional" nervous disease. He concludes that in adults an extensor response (Babinski's sign) never occurs in health; it is always indicative of organic disease. The pyramidal system need not be so injured as to show post-mortem lesions. An extensor response may be produced in any condition which greatly raises intracranial pressure, even if that condition does not cause a demonstrable lesion of the pyramidal system. For instance, an extensor response may occur in hydrocephalus, meningitis, cerebral tumor, etc.; in such cases the extensor reponse usually occurs only in comatose or semi-comatose states. It also occurs in convulsive conditions of organic origin; *e. g.*, in epilepsy, uremia, infantile convulsions, strychnine poisoning, etc. It never occurs in hysteria and allied conditions, unless some organic disease is also present. A flexor

[1] Review of Neurology and Psychiatry, May, 1904.

response is the normal plantar reflex of the adult; it may occur also in pyramidal disease: (*a*) In acute conditions if only a small amount of the pyramidal influx is removed by an organic cause; or (*b*) in chronic cases, even when a large amount of the pyramidal influx is removed. Under certain conditions it is sometimes possible to obtain an extensor response when the leg is extended, but when the thigh is flexed and rotated outwards and the knee bent, we may obtain a flexor response from the same foot; this may be termed the position of pyramidal equilibrium. The position of pyramidal equilibrium may occur when about five to ten per cent of the pyramidal fibers are thrown out of action in acute cases, but in very chronic cases it may be present when nearly half the fibers are destroyed. There is a contant tendency in the adult for an extensor response to give way to a flexor response; the more chronic the case, and the less severe the pyramidal lesion, the more rapidly will a flexor response be re-established, even though the limb remain severely paralyzed and contracted. The infantile response of children under the age of two years is dependent upon the immaturity of the pyramidal tracts; it resembles the response of pyramidal equilibrium rather than that of a full spasticity. The extensor response comes on simultaneously with the incidence of pyramidal disease. The reflex is not abolished by total transverse section of the cord, and appears to be less affected than any other reflex by "nerve shock." The plantar reflex may be absent in health when the foot is cold or damp; it is also frequently absent in hysteria, multiple neuritis, infantile paralysis affecting the leg and in severe tabes.

Byron Bramwell[2] reports four cases of hemiplegia in which there was an extensor response on the paralyzed side, but, on stimulating the sole of the non-paralyzed foot, he obtained a cross reflex in the paralyzed foot which was a normal flexor response. In such cases he thinks that the reflex impulse must pass from the opposite anterior horn of the spinal cord without forming a connection with the reflex arc in the gray matter of the paralyzed side. It is more probable, however, that the reflex impulse from the sound side stimulates the motor element of the normal flexor reflex arc, which has been damaged by disease, and causes it once more to perform its functions.

TRIGEMINAL NEURALGIA.

Verger[3] recognizes two types of trigeminal neuralgia, one of average intensity with a region of continuous pain, the other essentially paroxysmal, with excessively painful paroxysms separated by intervals of comparative calm, the true *tic douloureux*. The intensity and the resistance of the painful symptoms to treatment are the chief features of the second type. For this type the aid of surgery has been more and more invoked, until, at present, there is a tendency to resort to the most extreme surgical measures, removal of the Gasserian ganglion, which often proves fatal. Verger maintains, however, that there are neuralgias of central origin, where the cause is to be found in some lesion of the ganglion or the nerve roots, and neuralgias of peripheral origin, where the lesion is in the extremities of the nerve. The latter are cured by peripheral operations, and in such cases there may be an interstitial neuritis and lesions of the vasa nervorum. In these cases there may be secondary lesions in the ganglion from ascending neuritis. If this distinction can be made clinically, it is obviously of great importance in distinguishing the cases where a simple peripheral operation may prove curative from those where the more dangerous Gasserian operation is to be considered. Verger classifies his cases, twenty-three in number, by their behavior to injections of a two per cent cocaine solution in the painful spot. If the injection suppresses the neuralgic crises for the moment, the cause is probably in the periphery; if it does not modify the crises, the cause is higher up in the roots or ganglion. In the first group of cases, eight in number, the principal symptoms were the existence of a continuous pain between the neuralgic paroxysms in a zone more limited than the territory of distribution of the corresponding nerve; the possibility of exciting a crisis by chewing, sneezing, coughing, etc., and by exciting the painful zone; the constant existence of pain provoked by deep pressure on this zone; and the frequent occurrence of pain provoked at Valleix's points. There were frequently disturbances of sensibility to pricking and absence of spasmodic secretory symptoms. The pupillary reactions were normal. In ten cases cocaine had no effect. The characteristics of these cases were a long evolution, by degrees, with spontaneous periods of calm, which may be prolonged; the intermittent manifestation of the pains in the form of short paroxysms, appearing and disappearing suddenly and separated by completely painless intervals; the habitual absence of a true painful zone, the pain darting centrifugally from a definite point; chewing, swallowing and talking or taking too hot or too cold drinks habitually provoke the pain; the paroxysms cannot be provoked by peripheral irritation; there are no Valleix's points or defective sensibility of the face; there are tonic or clonic spasmodic phenomena in the course of the paroxysms. Furthermore, the pupils do not react to the paroxysm or to provoked pain, and there are paroxysmal secretory and vasomotor disturbances. In two cases of neuralgia due to lesions involving the roots the pain was continuous, with sensations of pulling, twisting and burning, with exacerbations coming on in crises at intervals of one or more days; there were marked disturbances of sensibility in the face and mucous membranes; external irritation had little influence in producing pain, and the pain involved the entire half of the face. In addition, there are often other focal symptoms, such as paralysis of the muscles of mastication. He reports three other atypical cases, chiefly

[2] Review of Neurology and Psychiatry, December 1903.
[3] Revue de Médecine, January, February, 1904.

hysterical, as examples of a neuralgia *sine materia*, a neurasthenic or hysterical topoalgia. In these cases the pain involves a larger and less definite area, it comes on independently of external irritation, its onset, evolution and disappearance are sensibly influenced by psychical causes, and it is often attended by the stigmata of hysteria. In these cases the pain often disappears permanently or for a long period after a single injection of cocaine. In many cases the diagnosis of the seat of the trouble can be made from the symptoms given above, but in doubtful cases it should be confirmed by the injection of cocaine *loco dolenti*. In regard to treatment the cases of peripheral origin are often materially benefited by the cocaine injections; if not, an operation affords a definite prospect of permanent cure. In cases of cerebral origin, Verger believes that Trousseau's old method of progressive doses of opium is most likely to cure. He condemns the progressive operations on the nerve beginning at the periphery and dividing further and further back, and he is very skeptical as to the advisability of removing the Gasserian ganglion. He finds a mortality of one case out of three and an absolute cure in one case out of five after such an operation.

BERI-BERI.

From a study of cases of beri-beri in the Kwala Lumpor jail in the Malay Peninsula, Wright [4] believes that it is an infectious disease due to a specific organism, as yet unknown, which exists in close, sunless and somewhat damp places, and gains entrance to the body by way of the mouth, giving rise to a local lesion in the stomach and small intestines; that it there produces a poison which enters the circulation and causes more or less extensive disease in certain neurones. He classifies the disease under three heads: The acute pernicious form, in which the organism produces inflammation or marked congestion of the mucous membrane of the stomach and duodenum, with other signs of infection, and a toxine sufficient to cause death in a short time; and acute and sub-acute forms, in which there is a lesser lesion of the stomach and a lesser effect upon the nervous system. These cases continue in a state of partial paralysis for a time and then recover, or they remain in a state of partial paralysis for months or years, and ultimately die of cardiac exhaustion or of some intercurrent disease. This second class of cases he terms beri-beric residual paralysis, which is different from the specific acute infection. He found that beri-beri had been epidemic and endemic in the jail for several years, and he placed monkeys in some of the cells which he believed were infected. A part of these were attacked by the disease, and the changes in the nervous system were studied. The earliest change was a fine granulation of the motor cells of the bulb and cord in the acute pernicious form. In the cases of residual paralysis the cells showed a complete chromatolysis, with a flattening of the nucleus and atrophy of the nerve fibers. In the long-standing cases the cell becomes vacuolated, its membrane ruptures, the cell is irregularly stained and the processes are lost or broken. The nucleolus is extruded. This stage is accompanied by distinct atrophy of many fibers, and, of course, by complete paralysis. He concludes that the organism is not one that affects or develops on food commonly used by man, and no special food is a factor in the production of the disease. The organism is, however, probably swallowed with food accidentally contaminated by it. It multiplies in the stomach and upper part of the small intestine, causes a local congestion or inflammation and elaborates a toxine, which, being absorbed, acts with varying force bilaterally and symmetrically on certain vital and ordinary neurones to give rise to the collection of symptoms known as beri-beri. The period of incubation is short. Rice cannot be seriously considered to have any influence in the causation.

[4] Brain, xxvi, 488, Part civ, 1903.

ARTERIOSCLEROSIS OF THE SPINAL CORD.

Pic and Bonnamour [5] have studied the special symptoms attendant upon arteriosclerosis in old people in twenty-eight cases. There is a morbid type, constituted essentially by weakness of the legs, exaggeration of the knee-jerks and a gait with short steps, which they term the spastic paresis of the atheromatous. This paresis comes on slowly and progressively, either independently, leading to a progressive contracture, or at the same time with various cerebral troubles, spasmodic laughing or crying and senile dementia. At the autopsy, beside a general atheroma, which is well marked in the arteries of the spinal cord, they find a sclerosis of the cord which is not systemic or diffuse and is most marked in the pyramidal tracts and the posterior columns. It is probable that this change in the spinal cord, which is the cause of the spastic paresis, is of vascular origin, like the lesions in the brain, which frequently accompany it. Instead of being general and diffuse, this sclerosis may be localized and give rise to conditions like those of the systemic scleroses.

THE ASSOCIATION OF IDEAS IN APHASIA.

Pierre Marie and Vaschide [6] have studied the association of ideas in nine patients with aphasia, who had previously been the objects of careful research in studying the clinical aspects of aphasia. They employed many of the well-known mental tests of psychology, with the intent to excite in them the association of ideas by fixing their attention upon a word or a fact and studying the association thus produced. The experiments were arranged so that the subject should respond by a single reaction or by all possible reactions. The result of their researches show that aphasics, whatever be the form of the trouble, have an exceedingly poor association of ideas. They find no image in the conscious sphere of their intelligence. The word, the sensory excitation or the act seem to have no

[5] Revue de Médecine, January, February, 1904.
[6] Revue Neurologique, 30 July, 1903.

power of association. By continuing the excitations almost nothing it awakened, and the images of their thought are clouded by these new excitements. The mental effort to associate an image or to seize it, either by contiguity or by any resemblance, is extremely poor in its results. There is a mental inertia. The subjects seem distracted, and affirm that the thought is as poor as can possibly be conceived. They can think of nothing, and the word, which in the normal man provokes many images, finds no concomitant in their thought, even after several minutes. Beside the verbal and visual association they tried to produce associations of ideas by representing some action. They obtained similar results with this difference, that the subjects, instead of associating the absent elements of the act or the elements which must take place in the evolution of the act, executed it automatically without being able to dissociate the elements. The patients were almost wholly unable to draw any advantage from assonances, consonances, contiguities, resemblances, etc., — in a word, from any of the elements which normal subjects use to facilitate association. In one case of traumatic aphasia, however, the association of ideas, although poor, was very nearly normal. In two cases of dysarthria they did not find any great loss of association, the patients behaving more nearly like normal individuals.

JACKSONIAN EPILEPSY.

Boué [7] has attempted to define the topographical value of the attack of Jacksonian epilepsy. He has studied fifty-seven cases where the attack began in the arm. From an analysis of these cases he finds that the attack does not indicate the precise location of the lesion in the brain, but that in ninety-two per cent it indicates approximately a lesion in the Rolandic or para-Rolandic region. The symptoms of the attack cannot give us any more definite idea of the localization. The cerebral lesions which produced partial epilepsy which began in the arm were divided as follows: (1) Motor zone: middle third, fifteen cases; lower third, five cases; upper third, three cases; the whole extent, five cases; ascending frontal (middle third), twelve cases; ascending parietal (middle third), two cases. (2) Frontal lobe: first frontal (posterior part), seven cases; second frontal (posterior part), one case; first and second frontal (posterior part), two cases; anterior part of the frontal lobe, two cases; lower part of the frontal lobe, one case. (3) Centrum ovale, two cases. Drivet [8] has continued the study, applying it to the cases beginning in the face and leg, fifty-seven cases in all. Of the cases beginning in the leg twenty-six were in the motor zone and nine outside. Of those outside the motor zone the lesion was in the temporal lobe in three cases, in the corpus callosum and optic thalamus in one, and in the cerebellum in two. In the cases beginning in the leg the lesion was in the motor zone in eighteen and outside it in four. He comes to the same conclusions as Boué, that in seventy-eight per cent of the cases the lesion is in the Rolandic area and in fourteen per cent in the para-Rolandic region, ninety-two per cent in all. The lesion in the Rolandic region is most often situated on the level with the center for the part convulsed or paralyzed, but it may be above or below. The study of the symptoms can furnish strong possibilities for localization, the most important symptoms being the aura and paralysis. The existence of aphasia may aid the local diagnosis, yet none of these signs is of absolute value.

EPILEPSY.

Turner [9] has studied the prognosis and curability of epilepsy in three hundred and sixty-six cases which had been under constant observation and treatment for at least two years. These cases were divided into three series according as they have responded successfully or otherwise to treatment, — the arrested, improved and confirmed cases. A family history of epilepsy is found more frequently among those who have become confirmed epileptics, but a hereditary history of epilepsy does not necessarily militate against the prospects of arrest or improvement of the disease in any given case. The age at the onset of the disease has a special bearing upon the prognosis. The most unsatisfactory cases are those in which the disease commences before the age of ten. They show the smallest percentage of recoveries and the largest of confirmed cases. If the disease arises between fifteen and twenty an almost equal percentage of arrested and confirmed cases may be expected. The greatest percentage of confirmed cases is found amongst those in which the disease begins between twenty-five and thirty-five, from which time onwards there is a steady increase in the expectations of arrest and diminution in the number which become confirmed. The duration of the disease influences prognosis to this extent, that the arrest or improvement is much more likely during the first five years than during the second five, but cases may be arrested even after twenty or thirty years. The greatest percentage of confirmed and the lowest percentage of arrested cases occur in patients with daily or weekly fits, while the smallest percentage of confirmed and highest percentage of arrested cases have only one or two fits a year. The character of the seizures is of influence, in that the major attacks are more tractable than the combined major and minor attacks, and the minor attacks occurring alone are least tractable. Marriage and pregnancy have little influence upon the fits, but the puerperium and lactation seem to favor their occurrence. The common incidence of epileptic fits is a regular periodicity. The fits may increase or decrease in number in a definite period of time, and a case of the increasing type may, by treatment, be converted into one of the decreasing variety. Long remissions induced either by treatment or spontaneously, lasting for several

[9] Lancet, 13 June, 1903.

years, are not unusual. They are of favorable prognostic value, but are not synonymous with a cure. A period of arrest for at least nine years has been fixed as the basis upon which a cure of epilepsy may be established. Adopting this definition, the writer regards 10.2 per cent of epileptics as curable. There are some cases which may be regarded as belonging to a curable type of the disease. These present little or no mental impairment, even though the fits may have existed for a long period. In the cases in which arrest took place cessation of the fits occurred during the first year of continuous treatment in over fifty per cent.

In a subsequent communication Turner[10] studies the influence of the mental condition in the prognosis of the disease, basing his conclusions upon the study of one hundred and sixty-one cases in the Epileptic Colony at Chalfont St. Peter. These cases were divided into four classes: (*a*) Intellectually normal 13.6 per cent. (*b*) With impaired memory 31.6 per cent. (*c*) Feeble-minded 25.4 per cent. (*d*) Demented 29.1 per cent. Sex has little influence upon the mental condition, although men are more often affected than women, yet the highest degree of dementia is somewhat more common in women. A family predisposition to epilepsy and insanity favors the development of some degree of mental impairment. The duration of the disease has some influence upon the mental condition; mental impairment is less common when the fits have lasted less than five years, just as mental integrity is less common when the attacks have continued for ten or more years; but mental health has been observed in cases lasting over twenty years, and mental deficiency in cases lasting less than five. The earlier the onset of the disease, the less the probability of an unimpaired mental state. The profoundest degrees of dementia are seen most commonly when the major and minor attacks co-exist. The *petit mal* seizures occurring alone are found with the lower grades of mental impairment. When the *grand mal* occurs alone, mental health is as common as mental deficiency. The more frequent the seizures, the more the degree of mental impairment. Fits recurring in series are accompanied by the high grade of dementia. The characteristic physiognomy of the disease is more common with the higher grades of dementia, but it may be observed in patients without any mental failure. The mental condition between the attacks seen in most cases of epilepsy is regarded as one expression of the disease of which the fits constitute another. The former, therefore, is not directly dependent upon the fits, and the frequency and character of the attacks, in association with the degree of mental failure, indicate the severity and intensity of the disease. The epileptic temperament, which is distinct from the mental impairment, is also described. Epileptics are usually sociable and possessed by a religious fervor, which often contrasts strongly with their actions, these being mostly perverted, passionate or even immoral. On the whole, they are self-opinionated and possess a conceit and assurance out of all proportion to their achievements. Their mental perspective is blurred and disproportionate. Their want of initiative is characteristic. Some are good workers, but most require supervision and direction. Many of them are lethargic and lazy, yet also hasty, pugnacious, contentious and difficult to live with. During a temporary increase in the frequency of the fits there is often a temporary dulling of the memory and finer mental faculties which should not be mistaken for beginning dementia. There is also often temporary irritability, lethargy, impairment of memory, and often a delusional state for a day or two before the onset of a fit.

Reports of Societies.

AMERICAN GYNECOLOGICAL SOCIETY.

TWENTY-NINTH ANNUAL MEETING, HELD IN BOSTON, MASS., MAY 24, 25 AND 26, 1904.

(Concluded from No. 3, p. 79.)

SECOND DAY. — (Continued.)

IMMEDIATE REPAIR OF INJURIES OF THE PELVIC FLOOR.

DR. HENRY C. COE of New York said that he had selected this topic in order to emphasize the fact that by careful attention to puerperal lesions at the time of their occurrence the patient could be spared much future trouble. He assumed that it was the usual practice of modern accoucheurs to repair injuries to the pelvic floor at once, but it was one thing to suture visible tears and another to repair deeper lesions. Even when perfect union of the lacerations was obtained, the occurrence of prolapsus, cystocele and rectocele, months afterward, proved that there had been some fault in the technique. The fact of the separation of the fascia and levatores ani muscles must be recognized as well as the superficial tear, especially after difficult instrumental deliveries. An illustrative case from the writer's practice was cited. The tendency of the accoucheur after a tedious instrumental case, in which both physician and patient were exhausted, was to spend as little time as possible in repairing lesions of the soft parts, trusting to aseptic technique to insure perfect healing. The writer was firmly of the opinion that it paid to do the work thoroughly at the time, unless the patient's condition was such as to render delay advisable. He had had such good results from immediate operations that the intermediate did not appeal to him.

In conclusion, he alluded to the fact that the modern accoucheur must be a surgeon as well as an obstetrician. It was expected of him to leave the patient in as good condition as he found her, otherwise he properly laid himself open to criticism.

UNIFORMITY IN PELVIC AND CRANIAL MEASUREMENTS.

DR. A. F. A. KING of Washington, D. C., read a paper on this subject, in which he reached the following conclusions: "(1) That at present the measurements of the normal and pelvic fetal head are indefinite and unsettled, and must continue to be so so long as they are determined by our present methods of mensuration. (2) The chief purpose in obtaining the

normal dimensions of these structures being for teaching and learning the normal mechanism of labor, it is proposed to adopt an ideal or hypothetical head and pelvis, upon the dimensions of which all authorities may agree. (3) In the adoption of such ideal structures, it is unnecessary and undesirable to define any measurement with exact precision — no fraction smaller than one fourth of an inch or than half a centimeter (in the metric system) being required. (4) Race variation forms no real obstacle to the proposed plan, and other apparent difficulties can be overcome. Finally, should the proposition meet with approval, it is suggested that this society take the initiative in bringing the matter in proper form before some forthcoming international medical congress for general adoption."

Accordingly, a committee was appointed by the president to consider the matter of uniformity in pelvic and cranial measurements, and report at the next annual meeting.

SYMPOSIUM ON NON-OPERATIVE LOCAL TREATMENT IN GYNECOLOGY.

DR. WILLIS E. FORD of Utica, N. Y., in reading the first paper, said that no one would deny that greater good had come from surgical treatment of diseases peculiar to women than was ever dreamed of by the early gynecologists who did not operate. No comparison of results could be made. He did not think it was true, however, that the specialty ought to become purely surgical. Pathology learned by pelvic and abdominal surgery ought to be clearer and better than was ever discovered post-mortem. It was fair to assume that men who did this work had a better idea of the natural history, progress and dangers of these diseases than those who did not operate; and that, therefore, the early treatment ought to be in the hands of men who were also doing surgical work. The nervous habit could not be cured by surgical procedure. What was commonly called neurasthenia was not a disease, but an established habit, possible only to those who had from birth an unstable or weak nervous constitution. Before the mental symptoms began was the time to prevent neurasthenics from becoming permanent invalids. That the nervous habit could not be cured by surgery had been proven by the fact that the removal of diseased ovaries and such like operations on epileptic women had not cured the epilepsy or neurasthenia. The argument, therefore, was that in those ailments that tended to disturb the emotions, especially those of the reproductive organs of men or women, the serious thing was not the pain experienced, but the permanent invalidism which was brought about by the protracted local sensations that in time disturbed the mental equilibrium and brought about the invalid habit. These local irritations ought to be treated by skilled gynecologists, and not allowed to develop either the mental or physical ailments which were so common a result. These arguments were enough to make the profession revive its interest in non-operative procedures. Recent displacements, especially in young people, and acute infections were mentioned as demanding non-surgical care early, if one wished to avoid the more serious ailments, and especially the most serious of all, the mental disorder called neurasthenia.

THE VALUE OF NON-OPERATIVE LOCAL TREATMENT IN PELVIC DISORDERS.

DR. WALTER P. MANTON of Detroit, Mich., said that the ignorance of proper methods, together with the fascinations of operative measures, had brought the local treatment of pelvic disease into disrepute. Three of the factors, which among others at the present time were largely responsible for the neglect of medical gynecology, were: (1) The average physician's lack of knowledge in the accurate diagnosis and local treatment of pelvic disease, (2) the allurements and fascinations of surgery, and (3) competition in the field of practice.

While it was true that no amount of instruction could impart a *tactus eruditus*, still any one could acquire a knowledge of the primary principles underlying the correct interpretation of gynecic ailments, if opportunity was offered for the practical examination of patients under competent direction. In ignoring the benefits to be derived from medicine, he was convinced that surgery had gone too far and that it had overshot the mark, but that the present tendency to operative measures in all conditions affecting the pelvic organs could not be ascribed so much to the good which surgery, rightly directed, was capable of accomplishing as to other elements which had entered into the case, was also evident. In the best of hands the results from local treatment in pelvic diseases were frequently slow in manifesting themselves, and discouragements were often met with, but in suitable cases persistent effort would ultimately attain the desired end.

The objects of local treatment were the relief of pain and irritation, often of a reflex nature; the allaying of congestion and inflammation; the absorption of the products of inflammation, and the reposition of displaced organs. In the regulation of the uterine functions, in congestions and mild inflammations of that organ and surrounding parts, and in displacements of the uterus, with and without adhesions, the application of proper local treatment was of signal value; while in prolapse of the tubes and ovaries, even in the presence of extensive adhesions, but without ascertainable morbid changes in the organs themselves, vaginal tamponade offered the simplest and most efficient means of reposition and cure.

TREATMENT PREPARATORY TO OPERATION.

DR. HENRY C. COE of New York introduced his remarks with the statement that while his early training had led him to believe that such treatment was practically indispensable in cases of so-called "cellulitis," subsequent experience had convinced him that this notion was not in accordance with pathology or common sense. He had expressed skepticism in this subject as long ago as 1886, when he read a paper on the "Exaggerated Importance of Minor Pelvic Inflammation," and subsequent experience had only served to confirm his opinion that old pelvic exudates and adhesions were not *per se* a contra-indication to operations on the uterus. Modern aseptic technique was a sufficient safeguard against danger from this source.

The reader contrasted the old practice of keeping a patient in a hospital for several months, with the preparatory treatment between each minor operation, with the present plan of performing combined operation at one séance, and sending out in three or four weeks. He questioned the actual value of the hot vaginal douche, local applications to the vaginal fornix, treatment of the ectropic cervix, etc., previous to trachelorrhaphy, since the diseased tissue would all be removed at once by amputation. At the same time he admitted the remarkable results often observed as regards the absorption of extensive pelvic exudates. Acute and subacute inflammations in and around the adnexa formed the real contra-indication to operation, and doubtless surgeons were not always

as careful as those of the former, more conservative generation in selecting their cases. Competition and the rush of modern life were responsible for some ill-advised operations, minor as well as major.

In regard to major operations the author thought that (excluding pus cases) general preparatory treatment of the patient was rather more important than local. He believed, however, that the admirable results obtained by the pioneers in the treatment of vesico-vaginal fistulæ were due to careful preparatory treatment, such as the division of cicatrices, stretching of the vagina, etc. Fortunately, we were seldom called upon to handle such complicated cases as those described by Sims, Emmet and Bozeman. With all our improvements in technique, we had not yet outgrown all the wisdom of our old teachers.

THE VALUE OF POST-OPERATIVE LOCAL TREATMENT.

Dr. J. Riddle Goffe of New York said the experience of all observers was that local treatment relieved congestion, pain and discomfort; inaugurated, hastened and accomplished the absorption of edema, plastic exudate, adhesions and pseudo-hypertrophy. If it would relieve these conditions, how much more certainly would it prevent them? It had been found serviceable in preventing the deposit of plastic exudate and the reformation of adhesions in cases in which these were present at the time of operation. It was especially valuable in cases subjected to vaginal section for the relief of sterility. The author reported several instructive cases to substantiate the points made in his paper.

THE IMPLANTATION OF THE HUMAN OVUM IN THE UTERUS.

Dr. Chas. Sedgwick Minot of Boston discussed this subject by request. He stated that the human ovum produced upon its exterior, during its earliest stages of development, a thick layer of cells, the trophoblast. The function of the trophoblast was to corrode away a portion of the mucous membrane of the uterus, making a cavity in which the ovum lodged itself. The trophoblast thereupon underwent a hypertrophic degeneration, such as to produce a series of irregular spaces, which persisted and became the intervillous spaces of the placenta. Papillary outgrowths of the chorionic mesoderm meanwhile penetrated the trophoblast, initiating the formation of the chorionic villi. The trophoblastic cells over each mesodermic outgrowth persisted in two layers, the inner cellular and the outer syncytial. These two layers represented the first stage of the villus ectoderm. Similar observations had been made upon primates, and were compared with those upon the human subject. He compared briefly the method of implantation in man with that in other animals, to show that the trophoblast was of general occurrence, and that by destroying uterine tissues it inaugurated the formation of the true chorionic placenta.

BATHING DURING THE MENSTRUAL PERIOD.

Dr. J. Clifton Edgar of New York said that in the consideration of this subject several questions suggested themselves, namely, first, the advisability of bathing of any description during the menstrual period, and if at all, to what extent. Second, the use of the bath in dysmenorrhea. Third, the use of Nauheim or other chemical baths or hydriatic procedures. Fourth, the risk of infection of the endometrium in intramenstrual tub bathing. Fifth, the influence of modern athletics on women, lessening the risk, if any, of intramenstrual bathing. These questions were submitted to the members of the society, from whom he had received one hundred and twenty-two acknowledgments.

From the replies received and the literature on the subject, he drew the following conclusions: "(1) All forms of bathing during the menstrual period are largely a matter of habit, and usually can be acquired by cautious and gentle progression, but not for every woman does this hold good; and surf bathing, where the body surface remains chilled for some time, should always be excepted. (2) A daily tepid sponge bath (85° to 92° F.) during the menstrual period is not only a harmless proceeding, but is demanded by the rules of hygiene. (3) In the majority of if not all women, tepid (85° to 92° F.) sponge bathing after the establishment of the menstrual flow, namely, second or third day, is a perfectly safe practice. (4) Furthermore, in most women the habit of using the tepid shower or tub bath after the first day or two of the flow can with safety be acquired."

THE STREPTOCOCCUS IN GYNECOLOGICAL SURGERY.

Dr. Hunter Robb of Cleveland, Ohio, stated that in order to arrive at some definite conclusions with reference to the Streptococcus pyogenes as a cause of death in his work, he had made an analysis of all his cases in which this organism had been found during the past six years. It was shown from observations that quite a large number of his patients died, and several were unimproved. It was also noticed that in the great majority of cases in which this organism was met with, there was a previous history of infection following labor, or an induced criminal abortion. In the past six years he had had 137 cases of abortion (including a few cases of labor) in which it was necessary to carry out some form of treatment. Of this number 104, or 75.9%, recovered; 17, or 12.4%, were improved; 1, or .8%, was unimproved, and 15, or 10.9%, died. In 16 of the 137 cases the streptococcus was found. The total number of all his cases in which the streptococcus was found was 40, consequently those in which this organism was found following an abortion or labor formed 40% of the total number of streptococcus cases from every source. Of these 16 patients (streptococcus cases) following abortion or labor, 4, or 25%, recovered; 3, or 18.75%, were improved; 9, or 56.25%, died. In the whole 40 cases from every source, in which the streptococcus was found, the results were as follows: Recovered, 20, or 50%; improved, 6, or 15%; deaths, 14, or 35%.

The streptococcus was found in the following combinations, given in order of frequency: (1) Streptococcus alone; (2) Streptococcus and Staphylococcus pyogenes aureus; (3) Streptococcus, Staphylococcus aureus, and Bacillus coli communis. In all these cases, except 3 in which they were obtained from the vagina, the organisms were obtained from the uterus, the adnexa, the cul de sac, or from several of these situations. In other words, they were proved to be present in places which were admittedly not their normal habitat.

In the past five years he had 724 abdominal sections, with a total number of 32 deaths, or 4.43%. In 7, or 21.9%, of them, the Streptococcus pyogenes was demonstrated. In all there were 19 cases of abdominal operations in which the Streptococcus was found. Of this number, 12 recovered, or 63.2%; and 7 died, a mortality of 36.8%.

THE NATURE OF THE INDICATIONS FOR OPERATION FOR FIBROID TUMORS OF THE UTERUS.

Dr. Chas. P. Noble of Philadelphia presented a table of the degenerations and complications in a series of 1,188 cases of fibroid tumors operated upon

by Martin, Noble, Cullingworth, Frederick, Scharlieb, and in a series reported by Hunner and MacDonald. Especial attention was called to the relative frequency of adeno-carcinoma of the uterus as compared with epithelioma of the cervix. The deduction drawn from this fact was that fibroid tumors were a direct predisposing cause of cancer of the cervix. A careful consideration of the facts presented in the table, said the author, should convince any one with an open mind that the classical teachings concerning fibroid tumors were erroneous. This teaching was that fibroid tumors of the uterus were benign growths, which usually produced but few symptoms, and which after the menopause underwent retrogressive changes, becoming smaller or disappearing; that the chief danger of fibroid tumors consisted in the fact that at times they caused hemorrhage from the uterus, and that rarely they caused trouble because of their size or because of pressure on adjacent viscera. An analysis of the 1,188 cases showed that because of the degenerations in the tumors, about 16% of the women would have died without operation; about 18% would have died from the complications present. In addition, it was well known that a certain percentage would have died from intercurrent diseases brought about by the chronic anemia present in many of these cases, and by injurious pressure from the tumors upon the alimentary canal and urinary organs. In brief, at least one third of the women having fibroid tumors, as shown by the author's table, would have died had they not been submitted to operation.

THE TREATMENT OF GONORRHEA.

DR. HENRY T. BYFORD of Chicago said there was dissatisfaction with prevalent methods of treating this disease. The desideratum was a local remedy that would rapidly destroy or remove the germs without injuring the protective epithelium, and a method of application that could be used by the patient which would not carry the germs to a deeper portion of the genito-urinary tract. He advocated prolonged irrigations with hot water as a basis, and spoke of frequent injections of hot water as a substitute for prolonged irrigations. He detailed his experience with urethritis in the male, and referred to hydrogen dioxide and unirritating germicidal solutions as substitutes for plain water injections, and gave their application to gonorrhea in the female.

The advantages of this treatment, when used early, were summarized by him as follows: "(1) It prevents the spread of the disease to adjacent parts. (2) It does not injure the epithelial covering, and it tends to limit the infection to the superficial areas. (3) It removes more germs and pus cells than either astringents or disinfectants can destroy. It acts in the same way as constant irrigation, both in aborting and arresting the progress of the infection. (4) It can be used more frequently than astringents or strong germicides, so that the parts can practically be kept free from pus and germs all the time, while the method of using germicides or astringents three or four times daily allows the germs and pus to accumulate and spread between injections. (5) In the male, and possibly in the female, peroxide injections may be substituted when the time and facilities for the hot water treatment cannot be had. When the discharge has become scanty and the injections cannot readily be used so frequently, a non-irritating solution of a silver salt can follow each hot water or peroxide treatment. (6) It may be used in connection with alphozone injections for the dissolving of germs and culture material not eliminated by the douches. (7) It does no harm. It can be combined with the internal or local medication when it becomes impossible to carry it out with the necessary time-consuming detail. It exemplifies the superiority of asepsis to antisepsis."

DR. PHILANDER A. HARRIS of Paterson, N. J., exhibited and described a new uterine obstetrical dilator.

OFFICERS.

The following officers were elected: President, Dr. E. C. Dudley, Chicago, Ill.; vice-presidents, Dr. Henry D. Fry, Washington, D. C., and Dr. Henry C. Coe, New York; secretary, Dr. J. Riddle Goffe, New York; treasurer, Dr. J. M. Baldy, Philadelphia.

Niagara Falls, N. Y., was selected as the place for holding the next annual meeting, in May, 1905.

Recent Literature.

Lectures on Diseases of the Nervous System. Second series. Subjective Sensations of Sight and Sound, Abiotrophy and other lectures. By SIR WILLIAM R. GOWERS, M.D., F.R.C.P., F.R.S. 12 mo. pp. 250. With 18 illustrations. Philadelphia: P. Blakiston's Son & Co. 1904.

These lectures have been published in various medical journals during the last ten years, and now appear in this convenient form. Of the ten lectures thus collected, the first two, the Bowman lecture for 1895 on subjective visual sensations and the Bradshaw lecture for 1896 on subjective sensations of sound, are the most important. The first lecture deals with the various spectra attendant upon migraine and the epileptic attack, and gives many curious studies of such spectra made by victims of migraine. The second lecture deals chiefly with tinnitus. The title of the third lecture is a neologism coined by the writer to express degeneration or decay in consequence of a defect of vital endurance. The other lectures are on myopathy, metallic poisoning, syphilis of the nervous system, syringal hemorrhage into the spinal cord, myasthenia and the use of drugs. As may readily be inferred they are all suggestive, and will prove profitable to every student of neurology.

Gynecology, being Vol. IV of The Practical Medicine Series of Year Books. Edited by EMILIUS C. DUDLEY, A.M., M.D., Professor of Gynecology, Northwestern University Medical School; Gynecologist to St. Luke's and Wesley Hospitals, Chicago; and WILLIAM HEALY, A.B., M.D., Instructor in Gynecology, Northwestern University Medical School. March, 1904. Chicago: The Year Book Publishers.

This little book of 216 pages contains well-edited abstracts from the current gynecological literature for the year 1903, and also several new illustrations by the talented senior editor, depicting some of his most recent methods of operating. This fourth volume maintains the high standard of the preceding numbers, and is to be highly recommended to the practitioner who is keeping abreast with the latest gynecological thought.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 28, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published a Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

POSTGRADUATE TEACHING.

THERE can be no question that the undergraduate departments of our larger medical schools are becoming year by year of relatively less importance. As medical schools have become more and more affiliated, both in fact and method, with universities, it has naturally followed that the teaching should more closely conform to the university type. One of the essential means of the development of universities in this country during the past decade has been the insistence placed upon the necessity of postgraduate work, both for the good of the community and the reputation of the institution concerned. We have therefore seen large postgraduate departments growing up side by side with the work of the academic course, at times, as some have thought, to the detriment of the latter. In any case what the university needs to develop is advanced work, and this certainly may only be attained through the offering of courses of instruction in special fields which go far beyond what should be required of the undergraduate student.

The same principle finds application in medical teaching. Each year demonstrates conclusively the absolute impossibility of covering the field of knowledge, except in the most superficial way, in the four years devoted to the undergraduate medical curriculum. In this short space of time the most that may be attained is a knowledge of the fundamental branches, with a certain amount of practical hospital experience, in the more general branches of medicine. Special work along any line is precluded, if the student is to devote anything like the necessary attention to the fundamental branches. The result very naturally is that those students who desire to deepen their knowledge in any particular line, and this forms an increasingly large contingent of our medical graduates, must either take certain specialized courses or else work out for themselves laboriously the desired information. It has therefore been a very natural result that so-called postgraduate courses should be instituted, which, together with summer courses coming essentially in the same category, constitute a mass of instruction wholly without and often beyond the limits of an ordinary medical curriculum. This tendency, now well marked, has certainly come to stay, and without any question will show definite development in the course of the years to come.

An occasion of much interest was the dinner and addresses given in New York in the earlier part of this year in honor of Dr. D. B. St. John Roosa, and in commemoration of the twenty-one years since the inauguration of postgraduate medical instruction in this country. This dinner was presided over by Dr. Osler in his usual happy vein, and the various speakers, chosen from different lines of professional work, each added his testimony to the value of postgraduate teaching as such, with particular reference to the work which has been done by the New York Postgraduate School, with which Dr. Roosa has for many years been identified. This school, as is no doubt generally known, is designed to offer instruction to practitioners of medicine in all the diversified fields of practice, and in this capacity it has ministered to the needs of a large number of physicians from all parts of this country and also from abroad. It is this sort of work, under somewhat different auspices, which our large educational institutions are now everywhere doing in connection with the more elementary work of the undergraduate student. That the two types of work, which as a matter of fact differ in degree rather than in kind, should be carried on under the auspices of a single institution seems in many ways eminently desirable, and we have no doubt that however useful distinctly postgraduate schools may continue to be, their absolute need is in great measure being obviated by the extension of instruction in university medical schools. Equipment of the most complete sort is naturally essential to advanced work, and this the university with its various correlated departments may best supply.

When we consider for a moment the importance of maintaining even average intelligence in all the branches of medicine, the necessity of the postgraduate department is forthwith apparent.

Doctors removed from the immediate stimulus of large medical centers simply must have opportunity for special instruction if they are to continue to do any sort of justice to the patients who come under their care. This opportunity is being offered now as never before, and unquestionably, as the courses are made more attractive and the deficiencies of knowledge are more and more forced upon the attention of conscientious physicians, there will be a still greater influx of men to take the courses offered. As a means, therefore, of keeping active, practising physicians in touch with medical progress, and as an absolutely essential method of educating young men in special lines of work; there is every evidence that the permanency of the postgraduate system is assured. It behooves our large institutions to give renewed attention to the matter, and to establish courses and methods of instruction which will redound not only to the advantage of the graduate student, but also to the dignity and authority of the individual institution. It is also to be expected that postgraduate work will tend to give opportunity to teachers of distinguished ability among our younger medical men. Such men also the profession at large needs, for the really good teacher now, as always, is a rare product.

ACUTE LEUKEMIA.

UNTIL recently leukemia was considered as a chronic affection, undergoing its evolution within at least one year or two, but lately cases of this disease reported in France and Germany tend to show that leukemia may develop, with considerable rapidity, in one or two months, and cases of the acute form of the disease are becoming so numerous that it may be questioned whether in reality it is not quite as common, or even more so, than the chronic type. In 1899 Gilbert and Weil published a paper in the *Archives de Medecine Experimentale*, in which they give an excellent description of the acute form. The début is sudden, while the fever appears and oscillates in a most irregular manner. The objective symptoms are most variable, according to the form of the acute process. In some cases attention is attracted by an enormous hypertrophy of the spleen and lymph-nodes, while in others there are profuse hemorrhages without any lymphatic reaction. By the enlargement of the spleen and lymph-nodes the diagnosis of leukemia can be made immediately, but in the latter class, if a blood examination is not made, the diagnosis will waver towards infectious purpura or severe forms of scurvy.

In acute leukemia with lymphatic hypertrophy the clinical picture is quite different from that presented by the hemorrhagic type of the disease. Simple inspection of the patient will reveal large tumors seated in the sides of the neck and in the axilla. The abdomen is voluminous, and palpation will discover an enormous spleen and enlarged liver. By auscultation a compression of the bronchial tubes from enlarged mediastinal lymph-nodes is apparent.

In the hemorrhagic forms, as, for example, in the case reported by Jeanselme and Weil at the Société Médicale des Hôpitaux, on Feb. 19, 1904, the lymph-nodes were not much enlarged and the spleen was not greatly hypertrophied. It would appear that in this case, at least, there was an attenuation of the lymphadenic process.

On the other hand, very accentuated hemorrhages of every description may be met with. There may be epistaxis or gastrorrhagia; extensive subcutaneous and submucous extravasations may attain such a degree as to form true hematomata. The patient expectorates large quantities of blood, while the gums are often bloody as in scurvy. In the case recorded by Jeanselme and Weil, the disease appeared to follow upon a pseudo-membraneous angina, for which reason a diagnosis of hemorrhagic purpura was at first made. This is frequently the error committed when a blood examination is neglected.

By an examination of the blood a mistaken diagnosis may be avoided, because it at once shows that both forms of acute leukemia, which appear so unlike, the one where enlarged lymph-nodes are apparent, the other giving rise to hemorrhages, are only modalities of the same affection, namely, acute leukemia. The blood of acute leukemia consequently presents certain characters of the highest importance, the dominating one being lymphocytosis. In order that this lymphocytosis may be of value, it is not necessary that it be absolute, that is to say, that the total number of lymphocytes must be very greatly increased. Thus Jeanselme and Weil found 1,453,000 red cells and 4,400 lymphocytes. But in such a case the proportion of lymphocytes in relation to the polynuclears is greatly increased and may attain 80%, while normally the proportion is just the reverse. What characterizes leukemia is the lymphocytosis, while the decrease in number of the red cells is of secondary importance as far as diagnosis is concerned.

PREVENTION OF TUBERCULOSIS IN ILLINOIS.

IT is always a satisfaction to note the increasing attention being given by boards of health, as well as by individuals, to the subject of the prophylaxis of tuberculosis. Not long since we commented on certain pamphlets relating to this and certain other matters of public hygiene sent out by the Oregon State Board of Health, so worded as to be intelligible to the laity, for whom they were, in fact, primarily intended. Within a few days there has come into our hands a pamphlet of similar sort entitled, "The Cause and Prevention of Consumption," sent out by the State Board of Health of Illinois. This pamphlet again is intended for the information of the public, and incidentally gives certain facts relating to the disease which are of wide general interest. During the past two years this board of health has been conducting careful researches on the prevalence of tuberculosis in Illinois, from which it has been learned that in that state consumption was responsible for more deaths than typhoid fever, scarlet fever, diphtheria, all forms of bronchitis, influenza, whooping cough, measles and smallpox combined. In 1903 seven thousand persons died from the disease, of whom forty-five hundred were between the ages of twenty and fifty. This fact means an estimated loss to the state each year of about thirty-six million dollars. The investigation also led to the conclusion that the disease is curable within the state, and it, therefore, urges the establishment of hospitals for tuberculosis which has hitherto not been granted by the legislature. In the pamphlet, which it is hoped may ultimately be in the hands of every citizen in the state, the early symptoms of the disease are narrated at some length, with the expectation that popular knowledge in this regard may lead to an earlier medical examination and consequent early treatment. The usual rules which the consumptive should observe regarding himself and also regarding his neighbors are laid down under prominent headings in unmistakable language. As we have repeatedly said in the past, we have no question that this method of disseminating knowledge, properly supervised, will ultimately lead to excellent results. Popularizing a disease, as it were, naturally detracts in great measure from its terrors, and if all classes in the community could be made to feel that incipient tuberculosis, while serious, is by no means fatal, we have no doubt that the campaigns of extermination would rapidly progress. Toward this end the various circulars, to which we have, from time to time, called attention, are certainly tending.

MEDICAL NOTES.

GUARDING AGAINST THE MOSQUITO. — It is reported that 100,000 yards of wire gauze are required by the Panama Canal Commission to guard against the inroads of mosquitoes during the work on the canal. It is said that 20,000 yards will be required for the hospitals and 75,000 yards for screening the houses along the canal. Steel wire galvanized screens are recommended.

DEATHS IN RAILWAY ACCIDENTS. — As stated by the Interstate Commerce Commission the railways of the United States for the fiscal year ending June 30, 1903, carried 694,891,353 passengers. The casualties for the year numbered 86,393, including 9,840 killed and 76,553 injured.

CHICAGO'S DEATH-RATE. — According to the Bulletin of the Chicago Health Department, Chicago's decreasing death-rate, which has been almost 29% since 1893 from the average of the previous ten years, is due almost wholly to the sanitary education of the public. The bulletin affirms that the Chicago public is better educated in sanitary matters than that of any other community, through its various local clubs, social settlements and kindred organizations. This statement is interesting, and we are not in a position to criticise it.

IMPERIAL CANCER RESEARCH FUND. — The third meeting of the General Committee of this Cancer Research Fund was held July 8, in London, with the Prince of Wales presiding. The King's sympathy and interest in the work of this organization is such that he has approved the addition of the word, imperial, to the official title. It will, therefore, hereafter be known as the Imperial Cancer Research Fund. The annual report states the character of the work done since the previous official communication. This has consisted in experimental work on the nature and processes of growth of cancer through researches on the lower animals. Among other results of importance is the demonstration of the existence of cancer in wild animals. Cancer has, therefore, been discovered to pervade the whole vertebrate kingdom, presenting constant fundamental characteristics, and it is concluded that

it is not permissible to seek for the causative factors of cancer outside of the life processes of the cell. Investigation bearing upon the diagnosis and treatment of cancer has also been carried out experimentally with as yet incomplete results. The following statistical investigation is also being prosecuted: Hospital statistics; occurrence of cancer in native races of the colonies and out-lying parts of the British Empire; statistics of assurance societes; recorded death-rate in Ireland and Great Britain, and the bearing of the foregoing upon the reputed increase of cancer. The report closes with the statement that there is nothing in the statistical investigation pointing to an actual increase in the number of deaths due to cancer. Little is said of the protozoön origin of the disease. Both the *Lancet* and the *British Medical Journal* of July 16 devote considerable space to a consideration of the foregoing report.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, July 27, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 44, scarlatina 5, typhoid fever 13, measles 30, smallpox 0.

THE GRADUATING CLASS OF HARVARD UNIVERSITY. — It is announced that of this year's graduating class of Harvard University 20 expect to pursue the study of medicine, 121 law, 128 business, 68 each, teaching and scientific pursuits, and the remainder various less popular employments. The contrast between medicine and law, two somewhat collateral professions, is particularly striking. No doubt law promises a more rapid and varied rise to fame.

NEW YORK.

A CENTENARIAN. — Mrs. Hannah Brown of Brooklyn, N. Y., died at the age of one hundred and one years, on July 22, two days after passing her one hundred and first birthday. She was born at Smithtown, Long Island, where her mother lived to be one hundred years old.

BEQUESTS TO HOSPITALS. — By the will of the late Sylvester S. Batton of Newark, N. J., $25,000 is left to charities. Among the bequests are the following: $5,000 each to St. Barnabas Hospital and the Home for Aged Women of Newark, and $5,000 to the Babies' Hospital of the New York Post-Graduate Medical School.

Obituary.

EDWARD W. LAMBERT, M.D.

DR. EDWARD W. LAMBERT, chief medical officer of the Equitable Life Assurance Company, died July 17 in New York. Dr. Lambert was born in Boston in 1831, and for the greater part of his active professional life has been associated with life insurance work. He was graduated from Yale in 1854 and from the College of Physicians and Surgeons in New York in 1857. He later prosecuted his medical studies in Bellevue Hospital, and has since been identified with the city of New York. At the time of his death he was one of the physicians to St. Luke's Hospital and to several smaller hospitals. He leaves a large family, three of his sons being physicians in New York.

Miscellany.

THE JAPANESE AS CHEMISTS.

PROBABLY no Eastern nation is more strongly represented than are the Japanese in the English annals of science, and more particularly in literature on chemistry. They possess an undoubtedly strong faculty for original research, and they combine this faculty with a sharp-sightedness as to the possibilities of practical application of the fruits of research. The Japanese chemist, in fact, unites the power of originality of the English chemist and the practical intuition of the German. At the University of Tokyo practical study is very much favored, and splendid facilities for work are provided in the laboratories and workshops. There are several distinguished Japanese chemists who are Fellows of the English Chemical Society and who were elected to the fellowship on account of the excellence of their contributions to original science. Many elaborate papers involving long and patient laboratory investigation are printed in full in the transactions of the society. The Japanese chemists discuss with a freedom which astonishes the Western chemist all the modern abstruse theories bearing upon the atomic theory, the constitution of matter, the theory of dissociation, and so forth. They write powerful dissertations on the views advanced by such esteemed thinkers as Ostwald, Arrhenius, Van't Hoff, Kelvin, Thomson, Lodge, Crookes, Ramsay and others, and have offered valuable criticisms on the methods of systematizing and compiling atomic weights adopted by Western chemists. Chemistry, of course, is a powerful weapon in war, and there can be little doubt that amongst other things which have so far contributed to Japanese successes is a sound knowledge of explosives, their composition, action and behavior under a variety of conditions. When there is no longer any need for the implements of battle, and may that soon be, we may be pretty sure that the same subtle insight which is so marked a feature of the Japanese intellect will turn with equal success to the application of science to peaceful pursuits. — *Lancet.*

CANCER RESEARCH IN LIVERPOOL.

A CANCER research fund has been established in Liverpool by the munificence of a donor who gave $50,000 as a memorial to his deceased wife. This is administered by a committee, consisting of Professor Carter, Dr. Barr, Prof. Rushton Parker, Prof. F. F. Paul, Prof. R. Boyce and Prof. C. L. Sherrington. A room to serve as a ward laboratory was established for research at the Liverpool Royal Infirmary, where also a number of beds were set aside for the clinical observation of cancer. The council of the University of Liverpool also granted the use of five large rooms in its laboratories for the prosecution of the inquiry. Dr. A. S. Grünbaum was appointed director of the research. He has just issued an interim report, which covers a period somewhat less than a year. Experiments were made with the cytolytic milk of a cow, and when it yielded no more milk, with its serum. Of two cases of cancer of the breast so treated, one was apparently arrested. Three cases of uterine cancer are being treated with horse serum. They all show signs of improvement. Another branch of the inquiry is directed toward the discovery of the cause of cancer. Dr. Grünbaum thinks that combination of causes, and perhaps not always the same combination, is necessary. If once a strain of human cancer can be secured, he says, we shall be appreciably nearer the goal. In the work both the developmental and parasitic hypotheses are kept in view. The recent evidence of the London observations in favor of a germinal theory raises the hope that a comparatively simple physiological cure may be possible, for experimental embryologists can, by simple means, alter the development of germinal cells. To promote interest in the inquiry, 2,000 circulars were sent out to doctors in the north of England and 1,000 to veterinary surgeons. But the responses have not been encouraging. A large number of tumors have been received from various hospitals for examination. Several, mostly malignant, from the horse, cow, sheep, dog, pig, cat, mouse and trout, have also been received. — *Journal of the American Medical Association.*

RECORD OF MORTALITY
FOR THE WEEK ENDING SATURDAY, JULY 16, 1904.

Deaths reported, 3,506; under five years of age, 1,363; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,325; acute lung diseases 252, consumption 344, scarlet fever 14, whooping cough 10, cerebrospinal meningitis 31, smallpox —, erysipelas 6, puerperal fever 9, measles 20, typhoid fever 38, diarrheal diseases 785, diphtheria and croup 68.

From whooping cough, New York 5, Chicago 3, Boston 1, Holyoke 1. From measles, New York 13, Chicago 2, Pittsburg 1, Lowell 3, North Adams 1. From cerebrospinal meningitis, New York 23, Baltimore 2, Boston 1, Worcester 3, Lynn 1, Revere 1. From typhoid fever, New York 10, Chicago 4, Philadelphia 10, Baltimore 1, Pittsburg 10, Boston 1, Somerville 1, Everett 1. From erysipelas, New York 2, Chicago, Philadelpia, Baltimore and Boston 1 each.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending July 2, the death-rate was 13.5. Deaths reported 3,953; acute diseases of the respiratory organs (London) 60, whooping cough 102, diphtheria 44, measles 180, smallpox 6, scarlet fever 25.

The death-rate ranged from 5.1 in Tottenham to 22.8 in Hanley; London 12.9, West Ham 11.8, Brighton 14.5, Southampton 8.8, Plymouth 13.7, Bristol 11.2, Leicester 13.0, Nottingham 15.7, Liverpool 17.7, Bolton 14.5, Manchester 19.0, Salford 14.8, Bradford 13.7, Leeds 16.0, Hull 18.1, Sheffield 12.8, Cardiff 10.1, Rhondda 15.8, Wigan 21.6, Merthyr Tydfil 9.3, Willesden 12.6, Birkenhead 16.3.

Correspondence.

THE HARVARD MEDICAL SCHOOL FROM A LAYMAN'S STANDPOINT.

BOSTON, July 15, 1904.

MR. EDITOR: The following conversation was overheard in an electric car on Huntington Avenue in the early summer.

"Oi say, mishter! Oi want to ask you phwat that building is. There, that one."

"That, madam, is a school-house."

"No, no! I know that, me children goes there to school. Phwat is the building beyant?"

"That is the Harvard Medical School."

"But he is on Boylston Street."

"Yes, but is going to move here."

"Och! poor thing! and must he move just loike us poor critters, because he can't pay his rint?" W.

METEOROLOGICAL RECORD.

For the week ending July 16, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING JULY 23, 1904.

C. M. DEVALIN, passed assistant surgeon. Detached from the "Albany" and ordered home to wait orders.

W. N. MCDONELL, acting assistant surgeon. Detached from the "Glacier" and ordered to the "Marcellus."

P. F. MCMURDO, acting assistant surgeon. Detached from the "Gloucester" and ordered to the Navy Yard, League Island, Pa.

W. H. BLACK, acting assistant surgeon. Detached from the Navy Yard, N. Y., Aug. 12, and ordered to the Naval Station, New Orleans, La.

E. S. BOGERT, Jr., surgeon. Orders of July 15 modified, ordered to continue duty at the Naval Academy.

L. W. CURTIS, surgeon. Detached from the "Buffalo" and ordered home to wait orders.

E. G. PARKER, passed assistant surgeon. Detached from the "Wheeling" and ordered to the "Buffalo."

R. L. SUTTON, assistant surgeon. Detached from duty with the Marine Battalion on the Isthmus of Panama and ordered to the Naval Hospital, New York, N. Y., for treatment.

C. C. GRIEVE, assistant surgeon. Detached from the Naval Station, Cavite, P. I., and ordered to the Naval Station, Guam, L. I.

D. C. CATHER, assistant surgeon. Appointed assistant surgeon, with rank of lieutenant, jr. grade, from July 9, 1904.

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING JULY 14, 1904.

STONER, J. B., surgeon. To proceed to Ocean City, Md.; Chincoteague and Wachapreague, Va., for the physical examination of certain keepers and surfmen of the Life Saving Service. July 9, 1904.

GUITERAS, G. M., surgeon. Granted leave of absence for seven days from July 14. July 11, 1904.

GRUBBS, S. B., passed assistant surgeon. To proceed to Moss Point, Miss., for special temporary duty. July 12, 1904.

BILLINGS, W. C., passed assistant surgeon. Department letter of March 28, 1904, granting Passed Assistant Surgeon Billings leave of absence for two months and three days, amended to read one month and twenty-eight days. July 8, 1904.

KORN, W. A., assistant surgeon. Relieved from duty at Philadelphia, Pa., and directed to proceed to Perth Amboy, N. J., for duty. July 12, 1904.

AMESSE, J. W., assistant surgeon. Department letter of March 26, 1904, granting Assistant Surgeon Amesse leave of absence for two months and fifteen days, amended to read two months and eleven days from May 1. July 9, 1904.

GLOVER, M. W., assistant surgeon. Granted leave of absence, on account of sickness, for seven days. July 13, 1904.

BAHRENBURG, L. P. H., assistant surgeon. Relieved from duty at Chicago, Ill., and temporary duty at Evansville, Ind., and directed to proceed to Delaware Breakwater Quarantine, and report to the medical officer in command for duty and assignment to quarters. July 9, 1904.

STIMSON, A. M., assistant surgeon. Upon being relieved at New Orleans, La., by Assistant Surgeon E. M. Steger, to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory for duty. July 12, 1904.

WARD, W. K., assistant surgeon. Upon being relieved at Reedy Island Quarantine by Assistant Surgeon G. L. Collins, to proceed to Washington, D. C., and report at the Bureau for instructions preliminary to assignment to duty in the office of the United States consul at Bridgeton, Barbadoes, British West Indies. July 12, 1904.

ROBERTS, NORMAN, assistant surgeon. Relieved at New Orleans, La., and directed to proceed to Evansville, Ind., and assume temporary charge, relieving Assistant Surgeon L. P. H. Bahrenburg. July 9, 1904.

COLLINS, G. L., assistant surgeon. Relieved from duty at Ellis Island, N. Y., and directed to proceed to Reedy Island Quarantine and report to the medical officer in command for duty and assignment to quarters, relieving Assistant Surgeon W. K. Ward. July 12, 1904.

STEGER, E. M., assistant surgeon. Relieved from duty at Ellis Island, N. Y., and directed to proceed to New Orleans, La., and report to medical officer in command for duty in connection with the examination of aliens, relieving Assistant Surgeon A. M. Stimson. July 12, 1904.

BROWN, B. J., JR., acting assistant surgeon. Granted leave of absence for twenty-one days from July 8. July 9, 1904.

CLEAVES, F. H., acting assistant surgeon. Granted leave of absence for twenty-three days from July 8. July 7, 1904.

GOLDSBOROUGH, B. W., acting assistant surgeon. Granted leave of absence for three days from July 13. July 9, 1904.

GREGORY, G. A., acting assistant surgeon. Granted leave of absence for seven days from July 5. July 9, 1904.

KEATLEY, H. W., acting assistant surgeon. Granted leave of absence for two days from July 8, 1904, under paragraph 210 of the regulations.

SAVAGE, W. L., acting assistant surgeon. Granted leave of absence for thirty days from Aug. 1. July 8, 1904.

STEVENSON, J. W., acting assistant surgeon. Granted leave of absence for ten days from July 11. July 13, 1904.

TAPPAN, J. W., acting assistant surgeon. Granted leave of absence for thirty days from July 11. July 6, 1904.

WELDON, W. A., acting assistant surgeon. Granted leave of absence for thirty days from July 8. July 13, 1904.

ALLEN, G. C., pharmacist. Granted leave of absence for thirty days from July 13. July 12, 1904.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., July 11, 1904, for the physical examination of an officer of the Revenue Cutter Service. Detail for the Board: Assistant Surgeon-General G. T. Vaughan, chairman; Assistant Surgeon A. J. McLaughlin, recorder.

Board convened to meet at the Marine Hospital, Baltimore, Md., July 12, 1904, for the physical examination of an officer of the Revenue Cutter Service. Detail for the Board: Assistant Surgeon C. W. Wille, chairman; Acting Assistant Surgeon J. G. Evans, recorder.

SOCIETY NOTICES.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS. — The American Association of Obstetricians and Gynecologists will hold its seventeenth annual meeting at the Hotel Monticello, St. Louis, Tuesday, Wednesday, Thursday and Friday, Sept. 13, 14, 15 and 16, 1904.

AMERICAN NEUROLOGICAL ASSOCIATION. — The American Neurological Association meets at St. Louis at the Planters Hotel, instead of in the World's Fair Grounds as orginally planned. The sessions will last from 9 A.M. to 1 P.M. daily. A general invitation to attend is extended to the medical profession.

RECENT DEATHS.

DAVID J. FITZGERALD, M.D., a prominent physician of northern New York, died at his home at Glens Falls, on July 17, of cerebral apoplexy. He was a native of Ireland, and forty-six years of age. He came to this country when young, and was graduated from the Fort Edward Collegiate Institute in 1876. In 1884 he was graduated from the Albany Medical College, after which he studied for a time at the New York Post-Graduate Medical School and Hospital.

GEORGE V. WENNER, M.D., of Milford, N. J., died, on July 19, from an overdose of cocaine. It is stated that for some time he had been experimenting on his own person with the drug, with a view to discovering the best means of antagonizing its toxic effects, and that he left a number of records of his observations. Dr. Wenner was forty years of age, and a graduate of the Medico-Chirurgical College of Philadelphia.

III. OPERATIONS FOR PERFORATION OF GASTRIC ULCER.
Summary Followed by Reports of Cases.

IV. OPERATIONS FOR GASTRIC HEMORRHAGE.
Summary Followed by Reports of Cases

V. GENERAL CONCLUSIONS.[1]

I. INTRODUCTION.

THE object of this paper is to review the surgery of benign diseases of the stomach at the two large hospitals in Boston during the last six years. Not long ago the medical aspect of ulcer of the stomach[2] at one of the hospitals was critically studied by a physician and surgeon, and it seemed fitting that the surgical side of the question should be as impartially treated. The above paper showed that the immediate success attending medical treatment of ulcer of the stomach in Boston was far below that usually given in the literature. Fifty-five per cent of the patients were discharged well from the hospital in contradistinction to Leube's 74% cured.[3] The ultimate results were still worse, and demonstrated that 56% of the ulcer patients were either dead, or had had stomach trouble referable to the ulcer since their discharge from the hospital. It is with patients similar to this 56% of medically unsuccessful cases that this paper deals. While the results are not as favorable as have been elsewhere reported, they represent the facts. Furthermore, they show the condition of the patient some time after the operation and not the immediate result alone. In the opinion of the writers the next six years will show remarkable improvement in this branch of surgery.[4]

* Read in part at a meeting of the Surgical Section, Suffolk District Medical Society, January 6, 1904.

[1] At a meeting of the Surgical Section of the Suffolk Branch of the Massachusetts Medical Society, held last winter, the question of operation in benignant gastric disease was discussed, and at its conclusion the suggestion was made that the results of the operations at the two large hospitals in Boston be combined and published. The writers are indebted to the chairman, Dr. F. B. Harrington, and the secretary, Dr. E. A. Codman, for permission to use the statistics of the Massachusetts General Hospital, which had been partially compiled for them by one of the writers, and to the Surgical Staff of the Boston City Hospital for permission to record their cases.

The writers further wish to express their appreciation of the kindness of Dr. Arthur T. Cabot, who read the manuscript before it was sent to the printer.

[2] Gastric Ulcer at the Massachusetts General Hospital, 1888–98. Greenough and Joslin. Amer. Jour. Med. Sci., August, 1899.

[3] Centralbl. f. Chirurgie, 1897, No. 28, p. 66.

[4] Should it meet with the approval of the surgeons at the Boston City Hospital and the Massachusetts General Hospital, it is the intention of the writers to record yearly the condition of all patients operated upon for benignant gastric disease since Jan. 1, 1898.

ANALYSIS OF THE STRICTURES OF THE PYLORUS. PYLORIC OBSTRUCTION.

Number of cases	21	
Number of recoveries	16	76.2%
Mortality	5	23.8%
Present condition: well	9	42.9%

On analyzing the fatal cases, we find that there were two fatal cases of pyloroplasty for stricture of the pylorus, Cases 3 and 17. We find that Case 3 had been exhausted by five years of vomiting and hemorrhage, and had had three terms of medical treatment during that time. She was in very poor condition for operation, and died on the fourth day, without recovering from shock.

Case 17 was of similar character, being that of a woman who had had daily vomiting and suffered daily stomach washings for a year, and had lost 40% in weight. She almost succumbed to shock on the table, and died on the fifth day of pneumonia.

As to permanent results of the pyloroplasties for stricture, Cases 8, 5 and 7 are classed as cured.

Case 8, a man who was in truly desperate condition at hour of operation, was well and at work four years after operation.

Case 5 was well four years after operation, and had worked steadily since.

Case 7 had vomiting and lived on soft solids for three years after operation, but in March, 1904, reported well.

As relieved are classed Cases 1, 2 and 4.

In Case 1 the relief only lasted a few months. In this case a further operation (gastro-enterostomy) ought to be considered.

In Case 2 relief after operation remained till two years later, when she died after removal of a ureteral calculus.

Case 4 was at work four years after operation, but obliged to live on soft solids.

Case 18 was not relieved.

In considering these cases in which relief was only temporary or did not occur, we must remember that the method of Heineke-Mickulicz, owing to the danger of recontraction, has been replaced by the gastro-duodenostomy of Finney, which affords a much larger opening and one much less likely to recontract. In these cases not relieved further operative procedure ought to be considered, as no other treatment affords any prospect of relief.

Of the gastro-enterostomies for pyloric stricture, ten in number, six are classed as cured, Cases 20, 37, 43, 10, 25 and 38.

Case 20, emaciated to the last degree at time of operation, was in good health, and had gained forty-nine pounds three years after operation.

Case 37 was well and at work five months after operation.

Case 43 was well six week after operation.

Case 10 was well at discharge from hospital.

Case 25 reported well three years after operation.

Case 38 reported well eighteen months after operation.

Of the gastro-enterostomies for pyloric stricture, there were three deaths, — Cases 13, 29 and 36.

Case 13 was operated upon twelve weeks after swallowing carbolic acid. Here probably faulty method was the cause of death, as no shock followed operation, but persistent vomiting. Anterior operation with the Murphy button was done. It is a question whether the opening was not made too high in the stomach. Case 29 was exhausted and emaciated. He had had seven weeks treatment in medical wards, and died. Died probably of shock after a quick anterior button operation. Case 36 died of inhalation pneumonia.

As not relieved are classed Cases 24, 26, 32.

Case 24 had a sponge removed six months after discharge, and pain and vomiting continued two years after operation (error in technique).

Case 26 "no better" two years after operation.

Case 32 died one month after discharge, and autopsy showed contraction of opening.

ANALYSIS OF THE CHRONIC ULCERS.

Number of cases	21	
Number of recoveries	16	76.2%
Number of deaths	5	23.8%
Present condition: well	7	33.3%

Review of the operations for chronic ulcer, 21 in number, shows that excision of the ulcer was done three times with no deaths; pylorectomy twice, both cases proving fatal; gastro-enterostomy 15 times, with 3 deaths; gastro-duodenostomy twice, with no deaths.

The fatal cases of gastro-enterostomy were Cases 16, 30 and 41.

Case 16 died on the fourteenth day of circular vomiting, constriction of the descending loop by the opening in the meso-colon, which was thickened by old adhesions and was not sutured to the stomach wall. This was an error in technique.

Case 30, a chronic alcoholic, died of delirium tremens.

Case 41. In this case the omentum adherent in the pelvis had to be tied off. A large portion tied with a coarse silk ligature became adherent to the line of union between the stomach and intestine and caused circular vomiting. An error in technique.

Of the pylorectomies, Case 12 died of shock after a difficult operation which was performed under the impression that the case was one of carcinoma. A gastro-enterostomy would have been, probably, a safer procedure.

In Case 19 a pylorectomy was also done, owing to supposed malignancy. Here, also, a gastro-enterostomy might have been preferable.

As cured of the excisions are classed Cases 9 and 11.

Case 9 was well three or four months after operation.

Case 11 required a year for convalescence, but worked after that steadily till the present, three years after operation, when he is well.

Case 22 is unrelieved, though a second operation showed the gastro-enterostomy to be patent.

Case 23 is no better than before operation.

Case 35 is classed as not relieved, his pain and distress having returned five months after operation.

Of the gastro-enterostomies, five are classed as cured, — Cases 21, 28, 34, 39 and 42.

Case 21 was in fine condition two years after operation.

Case 28 was well fourteen months after operation.

Case 34 was well six months after operation.

Case 39 in excellent condition four months after operation.

Case 42 in excellent condition two months after operation.

As relieved are classed three cases, — 14, 15 and 31.

Case 14 after relief for some time died of carcinoma, probably originating in the old ulcer, sixteen months after operation.

Case 15 had more or less vomiting for two years, but improved and was able to do her work. In February, 1904, three years and four months after operation, there was return of vomiting and bloody stools.

Case 31 (a case of perforation prevented by adhesion to anterior abdominal wall) had an abscess of the lung three months after operation, and died six months later.

As "not relieved" are classed Cases 40 and 33.

Case 40, a case of gastric tetany, from chronic ulcer, had successively a gastro-pexy, gastro-enterostomy, entero-enterostomy and gastro-duodenostomy (Finney) performed, and five months later was vomiting and still in hospital in poor condition.

Case 33 was better for four months, but later had return of vomiting and distress, and six months after operation was in poor condition.

Of gastro-duodenostomies, Case 27 is classed as relieved, which was her condition on leaving the hospital. No subsequent report.

Case 6, an acute dilatation of the stomach, was fatal, and is classed alone.

REMARKS AND CONCLUSIONS.

On review of these cases of the surgery of benign disease of the stomach, we find that we have in all of them been dealing with conditions which have been obstinate and irremediable by medical treatment. In stricture of the pylorus we have been dealing with a mechanical condition curable only by mechanical, that is, operative procedures. The final results fall into the classes given above, — a class who were cured, that is, restored to perfect health for a long period, those who were temporarily relieved, a small number who were not relieved, and the fatal cases.

In estimating the advantages which operation offers at the present time, we must take into consideration several facts. First, that these cases have been the early cases, operated upon during

the developmental period of gastric surgery in a conservative community. The technique has been in many instances faulty, owing largely to the inexperience of the operators, which was unavoidable. Lack of belief in the favorable results of surgical intervention has influenced the medical consultants to delay too long in calling in surgical consultation, and the surgeon himself has in many instances felt it so necessary to assure himself of the absolute necessity of undertaking an operation of such supposed magnitude that he too has lost valuable time and wasted the strength of his patients.

During the period that these operations have been done, the surgery of the stomach has progressed under the leadership of men who have devoted themselves to its study and practice, notably, Robson, Moynihan, Mayo, Mickulicz and Finney, until gastro-enterostomy and gastro-duodenostomy have become simple and safe procedures in the hands of those who are interested sufficiently in this subject to keep abreast of the modern technique. A knowledge of the pathological appearances *in vivo*, sufficient to enable the surgeon to decide accurately at the time of operation what measures to adopt, is also the reward of special attention and study of gastric surgery.

Medical clinicians who have interested themselves in the stomach are learning to differentiate those cases which are amenable to surgical treatment while there is yet time and opportunity for surgical aid; in other words, are alive to the advantages offered by surgery in suitable cases. Under these improved conditions the prospects for those patients suffering from stricture of the pylorus and chronic ulcer of the stomach are daily becoming brighter. Distrust and jealousy on the parts of both medical men and surgeons of each other's methods and results have in the past done much to limit the field of surgery, and miscalled conservatism, which conserves everything but the health of the patient, has also contributed to the bad results. Only by early consultation, courtesy, confidence and good faith on the part of physician and surgeon can this undesirable state of things be avoided. Its avoidance in the future will mean much to those afflicted with benign disease of the stomach.

Modern surgical technique, and, in particular, posterior gastro-enterostomy by the method of Moynihan, and the gastro-duodenostomy of Finney, have shortened the convalescence and improved the final results in gastric surgery enormously.

The judicious application of these procedures in the cases narrated in this paper might have lessened the mortality, increased the class of cures and diminished the number of those not relieved, besides shortening the immediate surgical convalescence of many.

II. Operations for Chronic Gastric Ulcer, Pyloric Obstruction and Acute Dilatation of the Stomach.

Name and Date	Sex	Age	Symptoms and Description	Condition Found Operation	Result	Remarks
J. Q. July, 1898. 1	F.	53	Gastric trouble for 5 years. Pain. Vomiting, without blood, of large quantities of old food. Stomach holds 3 quarts.	Stenosis of pylorus from thickened wall and adhesions. Pyloroplasty.	Disch. much rel'd.	Comfortable for some months after operation, then vomiting returned. "A living skeleton."
M. R. Aug., 1898. 2	F.	39	Gastric symptoms for 13 years. Vomiting, without blood, pain after eating. Peristaltic waves seen in epigastrium.	Pylorus stenosed, so that it will admit only a lead pencil. Gall bladder full of stones. Pyloroplasty. Gall bladder drained.	Well.	Second operation Dec. 23, 1899. Adhesions around pylorus divided. Well till Feb. 2, 1901, when she died after removal of calculus from ureter.
M. C. Sept., 1898. 3	M.	43	Burning pain in epigastrium and vomiting for 5 years. Loss of 45 pounds in weight. In bed at various periods, 5 to 6 weeks at a time. Three times in hospital for medical treatment. Hematemesis at various times. Stomach capacity, 5 pints. Free HCl. Had been relieved by treatment on medical side, but relapsed.	Stomach dilated and pylorus thickened. Pyloric opening size of lead pencil and not dilatable. Heineke-Mickulicz pyloroplasty.	Died. Sept. 15, in 4 days.	Shock followed operation and active stimulation employed. No vomiting. Gradual loss of strength, and death on fourth day.
N. H. Jan., 1899. 4	F.	28	Probable gastric ulcer 14 years previous. Since then chronic indigestion. Symptoms more acute for 3 months. Vomiting of old food, epigastric pain p. c.	Stenosis of pylorus and hour-glass stomach. Pyloroplasty and gastroplasty.	Disch. much rel'd.	Well for about a year. Since has had three attacks of pain and vomiting of 3 to 4 weeks' duration. Is now at work, but lives on soft solids.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Results	Remarks
C. D. G. Feb., 1899. 5	M. †	48	Swallowed muriatic acid 10 months past. Since then classical symptoms of pyloric obstruction.	Stenosis of pylorus. Pyloroplasty.	Disch. much rel'd.	Digestion good. Worked steadily since discharge.
H. C. Feb., 1899. 6	F.	19	Indefinite history of injury 14 months before by striking the epigastrium against a curbstone. Since then much distress with gas and after eating special food. Distress had been irregular. No vomiting of blood. The history suggested a neurotic tendency. Abdominal examination negative. Vomitus contained lactic acid but no free HCl. For 3 weeks irregular attacks of vomiting and epigastric pain. Feb. 15 a sudden collapse occurred. In the left hypochondrium a large tumor appeared.	Before operation a stomach tube was passed and failed to reduce the size of the tumor. At operation the stomach was found much dilated. Under ether a second attempt was made to empty the stomach by a stomach tube, but without success, though apparently no obstruction by stricture. On opening the stomach about a gallon and half of yellow fluid escaped. Gastro-enterostomy by Murphy button.	Died 3 days after oper'n.	Condition at end of operation very poor. On the third day after operation a mass similar to that found before operation appeared in the left hypochondrium. No relief from the passage of stomach tube. Collapse and death. No autopsy.
G. Z. 1899. Mar., 7	M. †	54	Chronic gastric trouble for years. For 10 months unable to work. Had vomited and passed blood by rectum.	Pylorus buried in adhesions, thickened walls causing stenosis. Pyloroplasty.	Disch. rel'd.	No work for 1 year, 5 months. March, 1901: Returned to hospital with pain in stomach and dark stools and vomitus. May, 1903: Improving. Some vomiting, without blood. Lives on soft solids. Able to work. March, 1904, well.
L. L. Nov., 1899. 8	M. †	39	Two years before operation symptoms began with epigastric pain and much vomiting. Grew worse constantly. Now much epigastric pain, vomits everything he eats. Vomitus generally dark, once or twice slightly tinged with blood. Free HCl. absent. Lactic acid present. Stomach capacity 37 oz. Lower border at umbilicus. Patient much emaciated.	Pylorus small, thickened, and opening admitted only a director. No ulcer found. Heineke-Mikulicz pyloroplasty. No shock.	Rel'd.	Dec. 31, 1903, was in fine condition. Had worked steadily since leaving the hospital.
J. S. Nov., 1900. 9	M.	37	Indigestion for one year. For last two weeks very uncomfortable, epigastric pain so severe that he was unable to eat. For two days vomited "coffee ground" material, and continued to vomit in spite of feeding. Nodule felt in pyloric region. Patient pale and emaciated. Free HCl. absent. Lactic acid present.	A large ulcer with much indurated elevated edges 2 in. in diameter on lesser curvature, ¾ in. from pylorus. Malignancy suspected. Ulcer excised. Hemorrhage controlled by continuous silk suture. Plastic to prevent narrowing on pyloric side. Resection of healthy tissue around ulcer was free on account of suspected malignancy.	Rel'd.	Disch. from hospital Jan. 16, 1900. Reported well soon after leaving hospital, when he moved to Philadelphia, where he could not be traced.
J. M. Feb., 1901. 10	M. †	31	Epigastric pain. Vomiting begun 9 years past. Gradually grew worse. Pain independent of food, but increased by lying on right side. Operation, — anterior gastro-enterostomy (Murphy button) — gave relief for about 2 years. Then old pain returned.	First operation, many adhesions and pylorus stenosed. Question of T. B. peritonitis. Anterior gastro-enterostomy. Murphy button.	Disch. Rel'd.	Second operation. Stricture of pylorus as before. Gastro-enterostomy opening had contracted to size of tip of little finger. Gastro-enterostomy (McGraw) at site of former anastomosis. Well Feb., 1904.
H. S. June, 1901. 11	M.	32	Symptoms began 6 months ago with sudden attack of faintness, epigastric pain, and vomiting. These attacks were frequently re-	Pylorus contracted too much to admit tip of finger. Ulcer extending ¾ inch along greater curvature. Excision of ulcer	Rel'd.	Convalescence 1 year, but since has worked steadily and without gastric discomfort.

CASE 11. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			peated and obliged him to leave off work for varying periods. Hematemesis occasional. Had six weeks careful hospital treatment without marked improvement. Pale, emaciated, slight epigastric tenderness.	and stricture, involving almost a complete pylorectomy, only a small strip being left posteriorly. Pyloroplasty.		
J. H. B. July, 1901. 12	M.	30	Three years previous to entrance sharp pain in the right hypochondrium. Vomiting. In following year and also one year ago had a similar attack. Three months ago — was seized with acute abdominal pain, lasting four weeks. Since getting up has had daily attacks of epigastric pain and much distress from gas. Vomiting in night. No hematemesis. Stomach holds 88 oz., and in the first washing considerable coffee-ground material. Visible peristalsis at times. Free hydrochloric and lactic acid present. Medical treatment was tried for eight days, and patient grew steadily worse. Exploration of stomach resulted in temporary relief. Numerous firm adhesions about the pylorus and the pylorus thickened. Improvement continued for 6 or 8 months. Three months after the operation had gained 45 pounds. Symptoms reappeared, and for 3 weeks before entrance there had been daily vomiting, ¾ hour after eating.	Under ether a mass in the region of the pylorus was palpable. At operation this pyloric mass was thought to be carcinoma. Pylorectomy was done, and in the operation the surrounding tissues and vessels were badly traumatized. Union, end-to-end, was accomplished by means of a Murphy button. Death all but occurred on the table.	Died within a few hours after oper'n.	No autopsy.
J. P. Aug., 1901. 13	M. †	61	Entered medical service July 5, 1901. Symptoms dated from 7 weeks before, when he had swallowed strong carbolic acid. Epigastric pain, vomiting continued in spite of medical treatment. He did not improve, and was transferred surgical on Aug. 6. Pale, emaciated. HCl. absent. Lactic acid present. Stomach holds 21 oz.	Pylorus thickened, and opening barely admitted a director. Gastro-jejunostomy with a Murphy button (anterior). No shock.	Died seventh day.	Vomited for 10 days until relieved by lavage. Then vomiting recurred, and gradually failed.
E. F. Sept., 1901. 14	F.	44	"Dyspepsia" for 3 years. Eighteen months ago fainted, and vomited a cupful of blood. Had rectal feeding for 3 weeks. After this epigastric pain. No melena. Vomiting, but not of blood since first attack. No loss of weight. Pale, tender below left costal margin, and some general abdominal tenderness. Free HCl. present. No lactic acid. Normal blood in stomach contents.	Pale, indurated ulcer on anterior wall, about midway of lesser curvature. Posterior gastro-enterostomy.	Rel'd.	In Jan., 1903, patient was explored for intestinal obstruction (partial), and carcinoma of peritoneum, stomach, omentum, colon, etc., found, probably having started from the old ulcer.
J. H. Sept., 1901. 15	F.	28	Since youth has had nausea and epigastric pain, vomiting usually after eating. Three years ago vomited blood, fainted and had bloody stool. Several simi-	Omentum found adherent to old laparotomy wound. Tied off and released. Pylorus admitted finger. No ulcer found at operation. Posterior	Rel'd.	Had more or less vomiting for two years after operation, but improved much in general condition, and was able

CASE 15. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			lar attacks since. Has lost considerable weight and noticed a tumor in epigastrium. Pale, emaciated. Tender mass felt in left epigastric region. Free HCl. present. Capacity, 920 cc. Laparotomy 4 years ago for disease of ovary.	gastro-enterostomy. No shock.		to do her work. Early in Feb., 1904, vomited for a week, with much pain in the stomach. Clots of blood in the stools.
E. S. Oct., 1901. 16	F.	19	For 4 months sharp epigastric pain and vomiting after every meal. Has fainted and suffered from dizziness and dyspnea. No hematemesis. No melena. Treatment in medical ward for 5 weeks with improvement, then relapsed, and vomited blood after solid food. Pain returned. Very anemic and weak. Systolic murmur at base.	Indurated area on greater curvature close to pylorus. Posterior surface of stomach adherent to transverse meso-colon by old fibrous adhesions. Cicatrix on posterior surface of stomach. Meso-colon considerably thickened. Posterior gastro-enterostomy. Opening in meso-colon not sutured to stomach wall.	Died in 14 days.	Did well for 4 days, except for occasional bilious vomiting. Then vomiting became severe and was not relieved by lavage. Grew quite weak, and on fourteenth day entero-enterostomy was done with the Murphy button. Operation showed obstruction of descending loop by thick edge of transverse meso-colon which had slid laterally. Death 8 hours after entero-enterostomy.
H. E. C. Dec., 1901. 17	M. †	50	Twenty-three years before entrance he had nervous dyspepsia and for two years much discomfort from gas. Since then stomach has been delicate. In 1899 jaundice, lasting for 2 months, and gallstones in the stools. Since 1900 there had been frequent attacks of pain in right hypochondrium. For 1 year stomach symptoms have been decidedly worse. Daily vomiting, often very large amounts of old food. Almost daily stomach washings. Weight has gone from 140 to 85½ pounds in the last 12 months. Visible peristalsis below umbilicus. Stomach held 58 oz. Analysis of contents showed the presence of free HCl acid. Hemaglobin 65%; white cells, 6,400. Was kept on medical treatment for 15 days, during which time he gained weight, but treatment did not relieve the evident pyloric stenosis.	Pylorus buried in adhesions, walls thickened and lumen constricted. Pyloroplasty.	Died 5 days after oper'n.	Autopsy showed a stenosis of the pylorus, due to an ulcer which extended out into the duodenum. The stitches of the pyloroplasty were holding and apparently the obstruction had been relieved. Also a pneumonia, which was cause of death.
L. Q. T. Feb., 1902. 18	M. †	43	For 20 years had had difficulty in emptying stomach. No vomiting, no pain. Stomach held 50 oz.	Lumen of pylorus small. No induration. Pyloroplasty.	Disch. rel'd.	"I am just as bad now as I was before the operation."
J. C. Apr., 1902. 19	M.	42	For 4 years symptoms of pyloric obstruction, — epigastric pain, vomiting of large quantities of old food, sometimes with blood. Stomach held 64 oz. Had lost 25 pounds.	Indurated mass at pyloric end of stomach on the anterior surface. Thought to be malignant. Pylorectomy, with end-to-end suture.	Died 9 days after oper'n.	The course after operation was uneventful until the seventh day, when a gastric fistula developed. Death 2 days later. No autopsy.
G. P. L. Apr., 1902. 20	M. †	41	For 15 years epigastric pain and vomiting, growing gradually more frequent. Excessive hematemesis on 2 occasions within 10 years. Vomitus constantly coffee colored. Has had hospital treatment for two periods	Pylorus much constricted. Lower border of stomach below umbilicus. Anterior gastro-enterostomy by silk suture.	Rel'd.	Had no gastric disturbance after leaving hospital. In Jan., 1904, was in perfect health and weighed 140 pounds, a gain of 49 pounds since the operation.

CASE 20. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			of several weeks. Much loss of weight. Now weighs 91 pounds. Much emaciated, pale. Lower border of stomach 2 inches below umbilicus, and peristalsis of stomach visible through abdominal wall. Free HCl. absent. Lactic acid, trace.			
D. C. July, 1902. 21	F.	48	Pain in left hypochondrium, eructation and occasional vomiting for 8 to 10 years. Four weeks before operation copious bloody vomiting, preceded by 10 days of severe nausea and anorexia. After this, bloody vomiting for 5 days. Pale, emaciated, epigastric tenderness.	Stomach appeared normal. Ulcer not found. Anterior gastro-enterostomy with suture. Pylorus patent and not thickened.	Rel'd.	Convalescence complicated by a parotitis which required incision. Left hospital Sept. 3 in good condition, with no gastric symptoms. Jan. 4, 1904, reported to be in fine condition.
T. McG. July, 1902. 22	M.	44	Headache and vomiting for 15 months. Vomited 5 to 12 times daily. Had been unable to work for over 6 months.	A few adhesions, but no definite induration about pylorus. Anterior gastro-enterostomy (McGraw).	Disch. rel'd.	Return of pain and vomiting, which have continued, despite a second operation, which showed patent anastomosis, and a third in which pus was evacuated.
J. L. July, 1902. 23	M.	41	Constant epigastric pain for 1½ years. Pain increased by taking food. Examination negative.	First operation 7 months after onset of symptoms; an exploratory laparotomy gave no relief. Second operation 10 months later. A few adhesions separated. No definite induration about pylorus. Anterior gastro-enterostomy (McGraw).	Disch. rel'd.	"I am no better than when I left the hospital, . . . stomach troubles me continually, . . . what I eat distresses me."
B. G. July, 1902. 24	M. †	32	Gastric pain for 10 years without vomiting. Pain came at irregular intervals and lasted a day to 2 weeks. In one attack jaundiced.	Pylorus indurated and lumen stenosed. Anterior gastro-enterostomy (McGraw).	Disch. rel'd.	Sponge removed 3 months after discharge. Pain and vomiting continue.
J. J. B. Sept., 1902. 25	M. †	36	Swallowed nitric acid 5 weeks previous. For about 3 weeks had vomited practically everything taken by mouth.	Pylorus and first part of duodenum were like a rope. Anterior gastro-enterostomy (McGraw).	Disch. rel'd.	Well. Serving a 6-months' term in Deer Island for stealing.
W. K. W. Oct., 1902. 26	M. †	42	Dyspepsia for 20 years. No history of any acute attack with vomiting of blood. Stomach held 55 oz.	Old scar at pylorus which constricted the lumen. Anterior gastro-enterostomy (McGraw).	Disch. rel'd.	"I don't feel any better than . . . the day I went in."
M. M. Nov., 1902. 27	F.	44	Vomiting and epigastric pain for 3 years. Hematemesis 2 days before entrance. No melena. Vomiting ½ to 2 hours after eating. Indefinite resistance and dullness in epigastrium. Loss of weight, 25 pounds in 3 years.	Dilated stomach. Distinct scar on pylorus. A few old adhesions of omentum to duodenum. Finney's operation of gastro-duodenostomy.	Rel'd.	Discharged from hospital Dec. 16. No gastric symptoms. Appetite and general condition improving.
L. F. Nov., 1902 28	F.	33	Four years ago a severe attack of vomiting and epigastric pain. Some hematemesis. Delicate stomach always. Right ovary and tube removed Oct. 20, 1902, for salpingitis. Ventro-suspension also performed 18 days after operation. Severe and persistent vomiting with hematemesis began and continued 10 days. Some blood in vomitus. Exhausted and emaciated. Tenderness in epigastrium.	Separations of old adhesions of duodenum and pylorus to posterior abdominal wall. Anterior gastro-jejunostomy with Murphy button. Patient in poor condition and operation had to be rapidly completed.	Rel'd.	Vomited almost constantly for six days after operation. Vomiting continued occasionally at gradually increasing intervals till Dec. 28. Discharged in good condition Jan. 10, 1903. No symptoms.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
G. N. T. Nov., 1902. 29	F. †	37	After birth of twins, 11 months ago, did not recover strength, and 9 months ago began to have attacks of vomiting once a week, gradually increasing during 2 months until they occurred daily. Five months ago began lavage, which relieved her. Has lost much strength and 20 pounds in weight. No solid food for 2 months. In medical ward from Oct. 4 to Nov. 25, 1902. At time of transfer surgical, on Nov. 25, was emaciated and exhausted.	No distention of stomach. Small intestine distended. Marked spasm of pyloric end and of duodenum, practically closing lumen for several inches. Anterior gastro-enterostomy with Murphy button. Good recovery from ether.	Died.	Five hours after operation began to fail, and died about 8 hours after operation.
J. F. May, 1903. 30	M.	29	Eight years ago for 4 weeks had epigastric pain and vomiting for 6 weeks. Hematemesis once during this period. Four days ago vomiting and epigastric pain returned. Tenderness in epigastrium.	Thickening of pylorus found, but no definite evidence of ulcer. Posterior gastro-jejunostomy by Mickulicz method.	Died.	Patient did not vomit, but did not sleep, became delirious, and steadily failed after operation. Died on third day. No autopsy.
A. R. June, 1903. 31	M.	50	Epigastric pain for 5 weeks, very severe for past week. Pale, emaciated. Dullness and marked tenderness in epigastrium, especially in left. Marked muscular spasm. Normal pulse and temperature.	Chronic ulcer of stomach on anterior surface near the cardia on the left, having a large perforation at its center, but adherent at point of perforation to abdominal wall. Much thickening of walls of stomach about ulcer. Gastro-plication. Posterior gastro-enterostomy by suture.	Rel'd.	Convalescence was slow on account of mural abscess which was opened on 8th day. The sinus was slow in healing. Was discharged on July 24, 6 weeks. Was up and about with no symptoms, and wound healed except for a small granulating area. Returned to hospital Aug. 13 and was operated Aug. 29 for abscess of right lung. Gradual convalescence. Small tumor excised from abdominal scar Oct. 22 and pronounced "Small, round, called sarcoma." Discharged Nov. 3. Up and about, though in rather poor condition and having a small sinus. Died at home about Dec. 10.
T. J. W. June, 1903. 32	M. †	58	Chronic epigastric pain without vomiting. No history of symptoms suggesting ulcer.	Pylorus small, nothing else remarkable. Posterior gastro-enterostomy (McGraw).	Disch. rel'd.	One week after discharge all symptoms returned and died 1 month later. Autopsy showed anastomosis contracted so as to admit only tip of little finger.
A. C. June, 1903. 33	F.	19	Pain and burning in epigastrium for one year. Had vomited blood. During attacks, epigastrium had been tender.	Stomach not remarkable. Posterior gastro-enterostomy (McGraw).	Disch. rel'd.	Better for 4 months. "After I eat I have the same bad pain, and I vomit most everything."
N. C. June, 1903. 34	F.	35	Six years ago attack of sharp abdominal pain with occasional hematemesis began and has continued with varying intervals since. Attacks last about 2 days. Last attack 2 weeks ago, accompanied by hematemesis. In good general condition, tender spot in epigastrium.	Stomach normal in size and contour. Some thickening at pylorus and a few slight adhesions. Posterior gastro-enterostomy with suture. Clamps used for hemostasis, linen thread used.	Rel'd.	Left hospital July 23 in excellent condition, with no symptoms, and was in excellent health on Jan. 5, 1904, 6 months later.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
J. McL. July, 1903. 35	F.	28	Gastric trouble for 10 years. For 3 months constant epigastric pain increased by food. In past attacks had vomited blood. Epigastric tenderness.	Old ulcer on anterior wall which had perforated and was buried in adhesions. Ulcer excised.	Disch. rel'd.	Well for 5 months, when pain returned and distress after any kind of food.
N. D. P. Aug., 1903. 36	M. †	52	Pain in epigastrium, nausea and vomiting for 3 years. Attacks of these symptoms have increased in severity and frequency. No hematemesis, no melena. Lower border of stomach 8 inches below umbilicus when inflated.	Pylorus found thickened and apparently obstructed. Anterior gastro-enterostomy with Murphy button at most dependent portion of stomach.	Died.	On second night after the operation vomited copiously and pulse was up to 135. On fourth day was comfortable and convalescence satisfactory. On eighth day developed a cough, became cyanotic and died suddenly. Autopsy showed an inhalation pneumonia.
J. W. Aug., 1903. 37	F. †	39	Distress after eating for 18 years. Pyrosis and sour eructations. Vomits large amounts every day or two. Daily stomach lavage for past 3 months has relieved her symptoms, but during this time she has lost 13 pounds. No hematemesis. Emaciated, but pulse good and in fairly good general condition. Gastric tympany a finger's breadth below umbilicus. Nodule sometimes felt in right side of epigastrium.	Stomach dilated, lower border below umbilicus. Marked thickening of pylorus, no lumen made out. Much induration of pylorus, suggesting possible malignancy. Pylorus undoubtedly almost completely occluded. Posterior gastro-enterostomy according to Moynihan's method.	Rel'd.	No vomiting after first night. Left hospital Sept. 12 in excellent condition. Soon went to work, and was well and at work in Jan., 1904.
S. I. McP. Aug., 1903. 38	F. †	24	Entered hospital in Sept., 1901. Symptoms suggesting gallstones. Operated and nothing found except a liver which was scarred so that diagnosis of probable syphilis was made. Re-entered July, 1903. Had taken mercury only for 6 months after discharge. For 3 months had been improved. Since then had suffered from dragging pain in epigastrium, belching of wind and nausea, but no vomiting. Good appetite. Medical treatment for 3 weeks without relief. Stomach held 36 oz. Analysis of contents showed no free HCl.	At operation many adhesions found around pyloric end of stomach. Posterior gastro-enterostomy, McGraw. (No mention of condition of stomach or liver.)	Disch. well.	
A. C. Sept., 1903. 39	F.	39	For seven or eight years has vomited pretty regularly 1 to 3 hours after meals. Steady pain—relieved only by vomiting—in epigastrium extending through to back. Treated at medical O. P. D. about 1 year. Diagnosis: Slight hyperacidity and gastroptosis. Lavage 3 times a week for just 3 months, has not relieved vomiting. In 5 months has lost 19 pounds.	Indurated area on anterior surface near lesser curvature. Pylorus much thickened, but not indurated. Enlarged glands in mesentery, one of which was excised. Posterior gastro-enterostomy with suture.	Rel'd.	No vomiting after operation. Left hospital Sept. 29, 1903, eating full diet and having no discomfort. Jan. 3, 1904, was in excellent condition.
L. L. Sept., 1903. 40	F.	23	Brought to the hospital on July 12, 1903, for tetany. Was said to have had a gastric ulcer ten years ago. While on medical side had epigastric pain, tenderness and vomiting. No hematemesis. No melena. Treated	Sept. 10, 1903, gastropexy. No evidence of ulceration found, no relief of symptoms. Oct. 7. Stellate cicatrix found on anterior surface near the greater curvature. Thickening at pylorus. Poste-	Rel'd.	Patient still in hospital to-day (Feb. 11, 1904). Gaining steadily, and vomiting only occasionally. Subsequently vomiting increased, and on March 23, was re-

CASE 40. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			from July 12 to Sept. 10, 1903, without much improvement.	rior gastro-enterostomy. Marked relief of symptoms till Oct. 31, 1903, when vomiting returned, and continued at intervals until Dec. 7, when entero-anastomosis was done with the Connell suture. A spur was found at site of anastomosis, probably obstructing loop. Temporary relief, followed by return of vomiting and symptoms of tetany. Jan. 6, 1904, Finney's operation. Pylorus found contracted and gastro-enterostomy wound closed so as not to admit tip of finger.		ported in poor condition.
E. G. C. Sept., 1903. 41	F.	44	Stomach trouble 20 years ago. For 6 months epigastric pain and nausea, increased by eating. Has vomited coffee-ground material several times. No melena. Loss of 25 pounds in weight. Insomnia. Pyrosis. Anorexia. For 6 months has had stomach washed every few days. Occasionally blood in the washings. Trouble began 20 years ago, with an attack of inflammation of the bowels. Is in fair general condition. Stomach not dilated. Slight tenderness in epigastrium.	Omentum found adherent to pelvic viscera and walls, evidently due to an old pelvic inflammation. Stomach normal size. Slight thickening on posterior wall, near greater curvature to the left. Pylorus normal. Omentum ligated with silk and freed from pelvic attachments. Stomach then turned up and posterior gastro-enterostomy performed by Moynihan's method.	Died in 8 days.	Excellent convalescence for 48 hours. Then patient began to look badly and vomit. Vomiting of greenish fluid became constant in spite of lavage, and condition became very poor. On Sept. 26 (eighth day) entero-enterostomy was performed, but patient never rallied, and died that evening. Autopsy: Several small ulcerations on the fundus. A rather large omental stump, with a coarse silk ligature, had attached itself to the anastomosis, and surrounded by this had formed a mass which obstructed the gut at the anastomosis. Gastro-enterostomy tight and also entero-anastomosis.
P. J. G. Oct., 1903. 42	M.	20	Admitted Oct. 13. For 1 week had had dull pain in right hypochondrium. 24 hours before was seized with sharp pain shooting into right scapular region, with chill and vomiting. Examination: Pale, sick looking, marked tenderness and spasm in right hypochondrium. Probable diagnosis: Cholecystitis.	Incision at outer border of right rectus. Gall bladder found normal. Appendix buried in adhesions very long and sharply bent on itself. Tedious appendectomy. The excess of clear fluid noted in peritoneal cavity, and on further examination pylorus found to be much thickened, especially in upper portion, and firmly attached to fresh adhesions to under surface left lobe of liver; fearing that detachment of the pylorus would almost certainly result in a perforation (there had probably been a perforation which was closed by immediate adhesion of the liver), the stomach and colon were turned up and a posterior gastro-enterostomy performed with suture.	Rel'd.	Vomited for two days after operation, but pulse and temperature remained good. Elevated to a sitting posture stopped the vomiting on the third day. Left hospital in good condition in 21 days; and 2 months later, Jan., 1904, was in excellent health.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
S. B. Oct., 1903. 43	M. †	30	Vomiting a short time after meals for two years. No hematemesis. No melena. In hospital 3 times and operation advised. Dilated stomach visible and palpable in upper left abdomen. Tetany.	Stomach found much dilated and pylorus obstructed, apparently by fibrous thickening. Posterior gastro-enterostomy	Rel'd.	No vomiting after operation. Solid food on tenth day. Convalescence delayed by a phlebitis of left leg. Left hospital on Dec. 19, with no gastric symptoms.

III. OPERATIONS FOR PERFORATION OF GASTRIC ULCER.

PERFORATION.

Number of cases	18	
Number of recoveries	5	27.8%
Mortality	13	71.2%
Present conditions — well	5	27.8%

It is certainly gratifying that surgery was able to save these five patients whose condition rendered recovery almost hopeless. In the next series of eighteen cases with perforation of a gastric ulcer operated upon at the Massachusetts General and Boston City Hospitals, we feel sure that the per cent of recoveries will be far greater, and we are led to this conclusion by the study of results obtained in the last six years.

Duration between perforation and operation. — The lapse of time between perforation and operation can be only approximately determined. In the five successful cases the duration was on the average fourteen and one-half hours, while in twelve of the fatal cases it was nearly twice as long, namely, twenty-five hours. Three of the fatal cases were operated upon under such favorable conditions as regards time — four, six, ten hours respectively — that their fatal issue demands especial explanation. The first of these patients (Case 18) walked to the Medical Out-Patient Department, but was allowed to depart with the condition undiagnosed. She shortly returned to the accident room and was promptly operated upon. This active exertion at the time of perforation had probably much to do with the final result. Case 12 was operated upon six hours after perforation, and did well until the eighth day. The stitches were then removed. Shortly after, in a fit of coughing, the wound was burst open, and, despite a prompt secondary operation, the patient rapidly failed and died. Case 8 was forty years of age, and had used whiskey to excess for one week previous to the operation.

Three cases were operated upon sixteen hours after perforation. Of these, one died upon the table (3) and another (11) in three hours, thus showing the desperate condition of the patients. The remaining patient (14) lived until the ninth day.

A study of the fatal as well as the successful cases plainly shows the advantage of early operation. This implies an early diagnosis, which, as a rule, is not difficult to make from the severe epigastric pain and the history of the patient. The importance of prompt action does not appear, however, to have been grasped by surgeon or physician in several instances. Case 1 was kept on the surgical side for some twenty-four hours after perforation took place, and Case 6 remained in a medical ward for the same length of time. Case 2 remained in the medical ward eleven hours after perforation. Case 17 while on the medical side developed sharp epigastric pain and abdominal rigidity at 6.30 P.M. The liver dullness became partially obliterated. Leucocytes = 17,500. At midnight the leucocytosis had slightly increased and the patient had vomited. Both medical and surgical house officers agreed in the diagnosis of perforation, and the condition was reported to the visiting physician, who advised medical treatment. The next morning the belly was much more distended, and an operation was finally performed. Death occurred in this instance in sixteen days from the general infection plus the acute infection due to a fecal fistula.

Age. — The average of the five patients who recovered was twenty-one years, while the average age of the thirteen fatal cases was twenty-nine years. Only one case above the age of twenty-one recovered, and this patient was thirty years old. Only three patients died who were twenty-one years of age or less. The influence of age appears striking in these 18 cases, but quite possible in a larger series it would lose its significance.

Sex. — There were nine male and nine female patients, and of the five patients who recovered two were female. Sex is therefore without import.

Condition since operation. — Five of the 18 patients left the hospital alive, and of these three have been continuously well. Of the remaining two, one patient (Case 5) developed intestinal obstruction twenty months after operation. This was relieved, and now, five and a half years after the first operation, he is in good health and at work. The remaining patient (7) had a recurrence of the ulcer, and at the present time is convalescing from a gastro-enterostomy.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
J. M. Dec., 1898. 1	M.	40	Operation 24 hours after perforation. Entered as an accident room emergency. For five weeks attacks of sharp epigastric pain, lasting a few hours. Two days before entrance confined to bed by this pain, which had	Operation about 30 hours after entrance. The abdominal cavity was filled with stomach contents. A perforation in the lesser curvature of the stomach was closed with Lembert sutures, and the general	Died.	Died a few hours after operation. Autopsy showed a general peritonitis.

			grown worse. Examination made by attending surgeon, and patient sent to ward. During the afternoon abdominal rigidity developed. Attempts were made to move the bowels. The following morning vomiting began and later became peritonitic in character. In the afternoon, pulse 140, with signs of general collapse.	cavity washed out with salt solution and drained.		
J. M. Jan., 1899. 2	M.	19	Operation about 15 hours after perforation. Acute indigestion for one week. Probable perforation a few hours before entrance to hospital. At entrance temperature, 95.4. Pulse 60. Blood count 43,600. Abdomen rigid. Kept in ward about 12 hours before operation.	Perforation the size of a lead pencil on anterior wall. General cavity filled with debris. Perforation closed, lavage, drainage.	Well.	Well, Jan., 1904.
C. L. Apr., 1899. 3	F.	22	Operation 16 hours after perforation. For three or four years much nausea and epigastric pain after eating; worse during last year. Vomitus sour. No blood vomited or passed by rectum. The night before entrance went to bed apparently in the usual condition. At 2 A.M. awakened by severe pain on the left side, and vomited three or four times. Deep inspiration caused acute pain and the attending physician diagnosed diaphragmatic pleurisy. During the day constant epigastric pain, increased by food, which also caused vomiting. A haggard expression and pale face. Rigidity of abdominal muscles; localized tenderness over the eleventh rib, near the spine. White count 23,200. Temperature 102.8. Pulse 120.	The general peritoneal cavity was full of debris, and on the anterior wall of the stomach at the cardiac end was a perforation.	Died.	Died on the table. No autopsy.
M. B. Apr., 1899. 4	F.	35	Operation 24 hours after perforation. Two years before entrance an attack of epigastric pain with vomiting. Ten months ago a similar attack which lasted several weeks. For five days severe epigastric pain after eating and frequent vomiting. Evening before entrance a sharp pain in the left hypochondrium, worse than ever before. At entrance patient was in state of collapse. Abdomen distended and tympanitic. Liver dullness obliterated. Abdominal wall rigid. White count 13,000. Pulse 120. Temperature 99.	Immediate operation. General peritoneal cavity filled with gastric contents. At the cardiac end a perforation of the stomach wall the size of a cent. Perforation closed, lavage, drainage.	Died.	Died the same night. Cultures from general cavity showed mixed growth of bacteria with abundant streptococcus hyogenes. No autopsy.
W. L. June, 1899. 5	M.	30	Operation 18 hours after perforation. Indigestion for one year. Twenty-four hours before operation vomited, after drinking moderately of beer. Eighteen hours before operation a sudden attack of epigas-	On opening abdomen in epigastrium, gas and bile-stained fluid escaped. General peritonitis. Pus and fibrin everywhere, and in pelvis. Induration of pyloric portion of stomach, and a perfora-	Rel'd.	Operated upon Feb. 16, 1901, for intestinal obstruction by a band. Jan. 5, 1904, 5½ years after first operation, was in good health and at work every day.

			tric pain, which was severe and continuous. Pale, eyes sunken, abdomen retracted and held in boardlike hardness. General tenderness, extensive in epigastrium.	tion ⅜ in. in diameter on anterior surface, ¾ in. from the pylorus. Gastroplication, folding stomach over on to first portion of duodenuem. Lavage of cavity and drainage of pelvis by glass tube passed through incision below umbilicus.		
M. McE. Dec. 1899 6	F.	20	Operation 72 hours after perforation. Four days ago suddenly seized with sharp pain in lower left chest, running up into shoulder. Two days ago severe pain in epigastrium caused her to go to bed. Vomited only once two days ago. Twenty-four hours ago vomited dark brownish material and spasm appeared in epigastrium. Peritoneal facies. Temperature 102. General abdominal spasm and tenderness, especially marked in epigastrium.	Median epigastric incision enlarged by lateral cut at upper end. Alimentary contents in peritoneal cavity. Perforation size of slate pencil in lesser curvature. Large ulcer surrounding perforation. Gastroplication. Lavage of peritoneum. Drainage of pelvis by glass tubes and gauze.	Died.	Shock, 24 hours after operation.
M. H. Jan., 1900. 7	F.	19	Operation 24 hours after perforation. Eighteen months ago in hospital for gastric ulcer with epigastric pain and hematemesis. Two subsequent attacks of pain and vomiting. Twenty-four hours ago acute violent pain in epigastrium, left abdomen and left shoulder. No vomiting, No syncope. Good color, does not look sick. Spasm and tenderness over left rectus and whole left abdomen. Extreme tenderness in epigastrium.	Median epigastric incision. Peritoneal cyst beneath abdominal wall. At pyloric end, close to lesser curvature, a perforation ¼ inch in diameter lying in the midst of edematous tissue. Gastroplication, after partial excision of ulcer. Lavage of peritoneum. No general peritonitis.	Rel'd.	Subsequently had a recurrence, and on Jan. 5, 1904, was recovering from a gastro-enterostomy.
J. K. May, 1900. 8	M.	40	Operation 10 hours after perforation. One week ago began to vomit in the evening. Worked until yesterday. Ten hours ago sudden sharp pain in abdomen, constant, general. Vomiting every few minutes. No blood. Has taken whiskey to excess during last week. Pulse 136. Pale, peritoneal facies. Abdomen slightly distended, tender and tympanitic.	Incision in epigastrium. Free brownish fluid in cavity. One inch from pylorus a perforation nearly ½ in. in diameter. Gastroraphy. Lavage and drainage of peritoneum.	Died.	Shock and peritonitis. Died in eight hours.
E. J. Oct., 1900. 9	F.	17	Operation 10 hours after perforation. Stomach trouble for a year. Pain, eructation. For one week severe pain in epigastrium. Sudden onset. Vomiting at first. At work till this A.M. Sudden attack of pain this P.M. at 1 so severe that she lay down on the floor for some time before getting strength to crawl to bed. Vomiting continued with a little blood. Looks sick. Temperature 102. Pulse 110. General abdominal tenderness and spasm, much more marked in epigastrium.	Median epigastric incision. Turbid serum free in peritoneal cavity. Flakes of fibrin on anterior surface of stomach. On drawing stomach out, slightly adherent to liver; near the cardia on anterior surface was an indurated area 1½ in. in diameter, having a pin point perforation at its center. Ulcer inverted, sutured with interrupted sutures of silk.	Rel'd.	Excellent convalescence. Went to work in 2 or 3 months, and in Jan., 1904, was in first-rate health.
N. O'C. Dec., 1900. 10	F.	21	Operation 48 hours after perforation. Stomach trouble for about 6 months, pain after eating, relieved	Short incision below umbilicus. Cloudy serum free beneath peritoneum. Diffuse fat necrosis of	Died	Died in 8 hours Shock and peritonitis.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			by vomiting. Two days ago, three hours after eating, taken with severe pain in upper part of abdomen. Vomiting. No blood. Pain very severe that evening. Chill yesterday. Pain continued. Flushed, face drawn. Tenderness and spasm all over abdomen, most marked in epigastrium.	omentum. Thin pus in pelvis. Adhesions in epigastrium, showing omentum surrounding a large pocket of bile and thin pus. Fibrin at pylorus and on anterior surface and upper border, close to pylorus, and on gastric side a clean punched opening about ¼ in. in diameter. Very little surrounding induration. Gastroplication. Drainage after irrigation.		
A. H. June, 1901. 11	M.	26	Operation 16 hours after perforation. Epigastric pain 8 or 9 years, and occasional vomiting of watery material. No hematemesis. No malena. About 16 hours before operation, at 8.30 in the evening, sudden severe pain in abdomen, with great prostration, sweating and vomiting. Pain severe all night, but better this A.M. Face drawn and anxious. Abdomen tender. Marked muscular spasm. Dullness in flanks, changing with position.	Median incision below umbilicus. Gas, pus and stomach contents escaped from peritoneum. Epigastric incision. Perforation found on lesser curvature, near pylorus, surrounded by considerable induration. Two silk sutures applied, but did not close it very well. Perforation walled off with wicks and glass drainage tube. Thorough irrigation and drainage of abdomen through another incision below umbilicus with tubes and gauze.	Died.	Died in about 3 hours. General peritonitis.
A. F. Aug., 1901. 12	M.	23	Operation 6 hours after perforation. Two years ago short attacks of pain in right abdomen, with vomiting and fever. Six hours ago while carrying heavy sac on shoulders felt something give way in abdomen, with pain so severe as to double him up. Vomited twice. Looks sick. Pulse 89. Temperature 100.8. Abdomen rigid. Excessive tenderness below umbilicus in median line.	Median incision, with umbilicus as central point. Thick pus in abdomen. Incision carried to ensiform. On anterior surface near greater curvature 2 inches from pylorus, a perforation 1 cm. in diameter. Induration 2½ cm. in diameter. Gastroplication. Irrigation. Suture without drainage.	Died.	Steady improvement for 8 days. Stitches then removed. Patient had a mild chronic bronchitis. In a fit of coughing burst open the wound and intestines protruded. Etherized and intestines irrigated and replaced. Considerable shock attended this procedure, and patient died in about 2 hours.
A. G. Oct., 1901, 13	M.	48	Brought to accident room at 4.30 A.M. During the past year attacks of epigastric pain. For 2 months the stomach symptoms have been more acute, requiring treatment in the Out-Patient Department. No attacks of sudden pain or faintness. At entrance, temperature 97; pulse 96. Examination of the belly was remarkable only from the presence of a small epigastric hernia. White count 12,000. Patient sent to the ward. Immediate operation advised at 9 A.M.	On opening the peritoneum, gas and milky fluid escaped. On the anterior wall of the stomach was found a good-sized perforation. This was closed with a silk stitch and the general cavity washed out. On the day after operation condition was satisfactory. On next day abdomen became distended, and an attempt was made under ether to drain the bowel by an artificial anus.	Died.	Died 2 days after operation. No autopsy.
K. H. June, 1902. 14	F.	18	Operation 16 hours after perforation. Entered accident room at 10 A.M. Temperature 102.4; pulse 146. Up to 3 months ago general health good, when for 3 weeks attacks of pain developed at intervals of 2 or 3 days in the region of the	Immediate operation demonstrated the general peritoneal cavity filled with turbid fluid. At the cardiac end of the posterior surface there was a perforation. This was closed and the cavity washed out. The after	Died.	Died 9 days after operation. Autopsy showed general peritonitis. The stomach wall, where the ulcer had been closed, had remained solid. On the anterior wall of the

CASE 14. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			umbilicus. Vomiting during the attacks, but without blood. Four days before entrance, after lifting a pail of water, patient was seized with acute pain in right side of abdomen. Pain was severe during all of that day and finally shifted to left side. At 6.30 P.M. on day before entrance she had a sharp pain in the umbilical region and vomited twice. In the night the epigastrium became tender. Examination showed general abdominal rigidity. Belly tympanitic. Shifting dullness in flanks and liver dullness obliterated. Color fairly good.	course was that of a typical general peritonitis.		stomach were multiple ulcers.
L. P. Oct., 1902. 15	M.	21	Operation 6 hours after perforation. Not well for 2 to 3 weeks. Afternoon of entrance had very acute abdominal pain without vomiting. At entrance temperature 101; pulse 100. Leucocytes 21,000. Shifting dullness in flanks. During examination vomited blood.	Immediate operation. Perforation on anterior wall at pyloric end. Small amount of turbid fluid which gave no growth on cultures. Perforation closed and posterior gastro-enterostomy, with McGraw ligature, lavage and drainage. Mixter tube in cecum.	Well.	Well Sept., 1903.
M. M. Jan., 1903. 16	F.	22	Operation 48 hours after perforation. "Stomach trouble" for many years. Two years ago was treated on medical side 46 days for gastric ulcer. For 2 days has not felt well. Strained herself while lifting, and soreness appeared in umbilical region. Vomited. Color pasty. Sensorium dulled. Abdomen distended, soft, except on right, where there is slight voluntary spasm. For 2 days pulse rose from 104 to 120, and temperature from 101.4 to 102.8.	Long itudinal incision over gall bladder. Gas and bloody fluid escaped from peritoneum. Grape seed removed from peritoneum. Incision carried to left, but patient's condition became so poor that perforation was not searched for. A thick wall cyst containing hemorrhagic and fine contents was packed with gauze. Query: Was not this the stomach?	Died.	Rallied from operation, but gradually failed and died 4 days later. No autopsy. Patient was admitted "surgical."
A. S. R. Jan., 1903. 17	M.	39	Operation 17 hours after perforation. For 7 years pain in the epigastrium about 2 hours after eating. At the end of 4 years the pain became worse, more frequent and associated with nausea and vomiting. Entered hospital in 1901. Hemoglobin, 75%; leucocytes, 9,900. Capacity of stomach, 3 pints. Free HCl. present. Lactic acid absent. By the hemin test blood was demonstrated in the stomach washings. The diet was regulated and in 9 days the patient was discharged, much relieved. Improvement continued for a year and one half. Six months before final entrance to the hospital, Dec. 30, 1902, there had been constant epigastric pain in attacks of 3 or 4 weeks' duration, followed by several shorter attacks. Once after passing a stomach tube he had vomited blood. For 3 weeks	On opening the abdomen, gas and stomach contents were found, as well as a perforation in the anterior wall of the stomach. Perforation closed and an omental graft applied; cavity washed out and drained. Pulse at end of operation 180, and condition poor. Thirteen days after operation a fecal fistula, not gastric, developed.	Died 16 days after oper'n.	The patient had apparently overcome the acute peritonitis, and death was due to the chronic absorption plus the acute process caused by the fecal fistula. Autopsy showed evidence of a general peritonitis and multiple small abscesses imbedded in meshes of fibrin around the spleen. In the left pleural cavity a moderate amount of blood-tinged fluid. The stomach showed at the pyloric end an old ulcer, 8 cm. in width by 7 cm. in length, extending in the direction of the lesser curvature. The base of the ulcer was fairly smooth, but showed several depressions. At the base of one of the

CASE 17. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			previous to Dec. 30, 1902, had suffered from epigastric pain. Pain not dependent upon food, and was relieved by sodium bicarbonate. No large amounts vomited. Hemoglobin 75 %; white count 9,600. During the day of entrance and until evening of the following day the patient was comfortable. At 6.30 P.M. sharp epigastric pain appeared, and abdominal rigidity developed. The liver dullness became partially obliterated. Leucocytes 17,500. At midnight the leucocytes had slightly increased and the patient had vomited. Iodophilia test gave slight reaction. Condition was reported to the visiting physician, who advised medical treatment. The next morning the belly was much more distended and operation advised.			deeper depressions, situated nearest to the lesser curvature and about 5 cm. above the pylorus, there was a small, blackish-red area. Section through this area showed that the depression reached quite to the peritoneal coat and was covered over by an adherent ridge of rather dense grayish tissue material. Fecal fistula in descending colon.
M. E. R. Jan., 1903. 18	F.	22	Operation 4 hours after perforation. Entered hospital as an accident room case. General health good until 2 months ago, when epigastric pain, gas and sour regurgitations developed. At times the epigastrium was tender, but on lying down tenderness and pain would pass away. No mention of vomiting, with or without blood. At nine o'clock on the morning of entrance the patient was seized with a violent pain in the right hypochondrium unaccompanied by chill or vomiting, and came to the Out-Patient Department, but her condition apparently did not warrant entrance to the hospital. Later in the accident room immediate exploration was advised.	At the operation an indurated mass without definite perforation was found in the region of the pylorus. Within this mass several small abscesses were evacuated. Abdomen wicked. On reaching the ward after the operation, the temperature was 104.8 and pulse 120. For 3 days the temperature remained at 104, 105, 106.	Died.	Died 3 days after operation, evidently from general peritonitis. No autopsy.

IV. OPERATIONS FOR GASTRIC HEMORRHAGE.

Ten cases; ten deaths. The series includes 6 females and 4 males. Four of the patients were under thirty years of age, 3 between thirty and forty, 2 between forty and fifty and 1 of unknown age. The youngest man of known age was twenty-eight, the oldest forty-six; the youngest female twenty-three, the oldest forty-seven.

In 9 cases gastric symptoms had existed for two to ten years. In one, a female of twenty-three, the hemorrhage ushered in the first gastric attack. A definite history of previous attacks of bloody vomiting was obtained in 3 cases. In 5 cases the hemorrhage came without other acute symptoms, and in 3 of these cases there was also a sudden collapse. Three times definite severe epigastric pain preceded the vomiting of blood or melena.

A lowered percentage of hemoglobin or pallor was noted in all cases. Epigastric tenderness was general. Once there was definite tenderness in the back, on the level of the eleventh rib.

In the case of the female in her first attack the operation was within thirty-six hours of the hemorrhage. In the other cases the time of operative interference varied between two and thirty days after the beginning of the acute attack.

The general condition of each patient before operation was desperate, as is shown by the fact that 6 of the cases were medical transfers which were regarded as cases of forlorn hope and the remaining 4 were admitted as surgical emergencies of the most severe type.

Eight times the stomach was incised and explored by invagination of the wall. Twice no general examination of the interior was made. Of the 8 careful explorations 3 were negative; 1 other was negative, save for two bleeding points which were possibly due to manipulation; 1

showed numerous areas which seemed to ooze; 1 had pyloric thickening; 1 showed an ulcer on the posterior surface without any evident point of hemorrhage, and 1 had an ulcer on the lesser curvature with a definite point of hemorrhage. In the two operations where no exploration of the interior was made, one stomach showed at operation an induration on the anterior surface near the pylorus and the other a thickened pylorus.

Twice the operation consisted in the repair of the stomach wall after incision; twice the ulcer was excised; once the ulcerated area was turned in with a purse-string suture; once the stomach was sutured to the abdominal incision and tamponed with gauze; and four times a gastro-enterostomy was done.

Death occurred from three hours to eight days after the operation, seven dying within seventy-two hours.

The cause of death given in order in the cases in which an autopsy was made was gastric hemorrhage, general peritonitis following a second operation, gastric hemorrhage, gastric ulcer with probable bleeding point at its center combined with operative shock, inhalation pneumonia.

The probable cause of death, given in order, of the cases in which no autopsy was made was continued hemorrhage with inanition, acute hemorrhage, continued hemorrhage into bowel, probable acute hemorrhage, shock of operation in the extreme condition.

The large proportion of males in this series, a ratio of 2 to 3, is a striking illustration of the accepted fact that gastric hemorrhage in men is a much more serious symptom than in women.

The previous histories and entrance examinations are not remarkable. Only the severity of the symptoms differentiates them from routine gastric hemorrhage cases.

Operation was undertaken at a time when the resistance of the patient had been reduced too far. This in our opinion was due primarily to the belief that gastric hemorrhage is a condition for medical treatment alone, and rarely to unavoidable circumstances,

Isolated instances of operations "*in extremis*" are justified, but to continue to interfere in these cases of gastric hemorrhage only at the point where all hope of recovery under medical treatment had gone would seem to be a questionable procedure and to offer practically no advantage to the patient. Operations must be attempted before the resistance has been reduced to the extreme, and that time, it seems to us, must be determined by the internist and the surgeon working together. Their combined judgment of general condition and probable prognosis under either method of treatment will determine in each case the advisability of operative interference.

The findings at operation are disappointing, in that autopsies when made and the subsequent course of the case so generally disproved their negative reports.

In the 2 cases in which nothing was done but to repair the wounds of the stomach wall, certainly no advantage was given the patient. The method of suture to the abdominal wall and tampon of the stomach, considering the necessary course of the wound, must be classed as a procedure of questionable value. Excision or turning in of the ulcers as performed in 3 cases, while apparently indicated, is certainly not the accepted doctrine of to-day. Hence in 6 of the cases the operation was theoretically in error. Gastro-enterostomy which was done four times was equally unsuccessful. Why this was so, probably depended upon the condition of the patient, but the one autopsy finding available is suggestive, that is, "the anastomosis admitted the passage of the middle finger." As the whole virtue of this operation depends on the theory of free and easy drainiage of the stomach cavity, the explanation is suggested that the location and size of the anastomosis may have been at fault. The failure to relieve the irritation of the ulcer probably accounts in at least some cases for the continued or recurrent bleeding.

The "bleeding point" is so seldom found, and the results of a hurried examination so unreliable, that a prolonged exploration in these hemorrhage cases where operative shock may be such a factor is not justified. A properly placed gastro-enterostomy with an ample opening is, in our opinion, the operation which offers the greatest hope of success.

The cause of death may be stated in general as a continuation of the conditions existing before the operation plus the shock of operation. The inhalation pneumonia attracts notice from its presence in so small a number of cases and serves to emphasize the importance of the consideration of this risk in stomach surgery. The one general peritonitis which followed a second operation after the breaking open of the wound must be regarded as an unfortunate calamity that is not likely to occur again. Three deaths in females under thirty years old is in marked contrast to the results of medical treatment as shown by statistics. Two of these cases, however, were admitted to the medical wards and transferred after treatment for five to eight days as practically hopeless.

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			back over eleventh rib. Blood showed hemoglobin 35%; white corpuscles 4,800; reds 3,324,000. Medical treatment for 48 hours without relief. Transferred for operation, with pulse of 120 and temperature 96°.	Condition at end of operation, poor.		classical symptoms of hemorrhage. Autopsy demonstrated a hemorrhage from the gastric ulcer on the anterior surface of stomach. General peritoneal cavity clean.
C. C. Dec., 1898. 2	F.	29	For 3 years epigastric pain about 30 minutes after eating. Eighteen months before entrance vomited considerable coffee-ground material. Two days ago vomited 4 oz. more or less blood, and fainted. Entrance examination negative, except for localized tenderness in epigastrium. Hemoglobin 70%. No free hydrochloric acid in stomach contents. Rectal feeding for five days, but continued to vomit bright blood. Transferred for operation with pulse of 140.	No definite area of ulceration. Exploration of stomach showed several areas which seemed to ooze blood. Stomach sutured to abdominal wall and packed with gauze.	Died on the eighth day after operation.	Gauze tampon in stomach apparently caused no special symptoms. Packing removed after 48 hours, during which time the general condition was satisfactory. Removal of gauze followed by continued hemorrhages and usual sequelæ of gastric fistulæ. Death apparently due to hemorrhage and inanition. No autopsy.
T. McG. Mar., 1901. 3	F.	33	For 2 to 3 years distress after eating. On morning before entrance, without other symptoms. Vomited a cupful of blood. Entrance examination negative. Medical treatment for 22 days without relief. Pulse suddenly went from 70 to 140, abdominal pain increased, localized tenderness developed in epigastrium, and vomiting became more nearly constant. Transferred to the surgical wards, where rectal feeding was continued for 48 hours. Condition before operation extremely poor.	No definite point of hemorrhage or perforation. Adhesions about pylorus and pyloric end of stomach thickened. Anterior gastro-enterostomy with suture.	Died 3 days after operation.	After operation the stomach was less irritable. On the evening of the third day the pulse suddenly shot up, and this, with other signs of collapse, suggested another hemorrhage as the cause of death. No autopsy.
W. R. May, 1901. 4	M.	28	For 3 years attacks similar to present one. Had been in hospital 3 times for treatment of gastric ulcer. Medical treatment for 1 month, during which time hematemesis, melena and hiccough persisted. Systolic murmur at apex. At surgical transfer there was epigastric tenderness, and stomach tympany extended below umbilicus.	Exploration of stomach and as much of the duodenum as possible was negative. Gastro-enterostomy with suture.	Died 5 days after operation.	Vomiting continued, and 3 days after operation the patient strained the wound open. Chloroform and suture of wound. Vomiting continued. Autopsy showed slight lesion of mucosa 1 cm. square, situated 4 cm. from the pylorus and general peritonitis.
M. S. Aug., 1901. 5	F.	39	Indigestion for 2 years. Two weeks ago had severe epigastric pain after eating. 48 hours ago vomited blood and began to have bloody stools, which continued up to entrance to hospital. At entrance, there was pallor of skin and mucous membranes and general tenderness over abdomen, but most marked in the epigastrium. Pulse 88, irregular and intermittent.	Median epigastric incision. Stomach explored, but no evidence of ulcer. Duodenum also explored as far as possible, but with negative results. Anterior gastro-enterostomy with Murphy button.	Died on 3d day after operation.	Rectal hemorrhages continued after operation. Occasional vomiting. Pulse and temperature gradually went up. No autopsy.
M. R. Sept., 1901. 6	F.	23	Previous history unimportant. 36 hours before entrance vomited blood, and had a bloody stool. Hematemesis repeated twice. Evening of entrance vomited about a basin full of	Subcutaneous infusion of salt solution before operation. Exploration of stomach failed to show any ulceration. Two small bleeding areas near edge of incision excised.	Died on 3d day after operation.	Rallied from shock, which was extreme, but the following day began to grow weak, pale and very restless, and failed to respond to stimula-

CASE 7. — *Continued.*

Name, etc.	Sex	Age	Symptoms, etc.	Condition, etc.	Result	Remarks
			blood, and pulse became rapid, feeble and thready.			tion. It was a question whether the bleeding points which were excised, might not have been caused by the trauma of the operation. No autopsy.
M. B. Sept., 1901. 7	F.	25	Had been in hospital 6 years before for chlorosis, and 1 year before for gastric ulcer. For 13 days before entrance vomited all food. Once vomited a cupful of bright blood. Medical treatment for 8 days without relief of vomiting or hematemesis. Transferred for operation with sub-normal temperature, pulse of 150, and epigastric tenderness.	Not much blood in stomach and no definite bleeding point. On posterior stomach wall, close to the center of the lesser curvature, was an ulcer 15 by 12 mm. Ulcer excised. Stomach wall sutured in layers.	Died on second day after operation.	Patient did not rally from the shock. Pulse and temperature rose. No response to stimulation. No autopsy.
M. L. Apr., 1902. 8	F.	47	Chronic indigestion for 6 to 8 years. Symptoms more marked for 10 months. Vomiting of bright blood and collapse 4 days before entrance. Two days after entrance vomited half a pint of bright blood. Operation 8 days after her first gastric hemorrhage. Patient in state of moderate collapse. Hemoglobin 75 %.	Pyloric end of stomach indurated. Posterior gastro-enterostomy with the aid of a bone bobbin.	Died 2 days after operation.	After the operation hematemesis continued. Autopsy showed a small ulcer on the anterior surface of the stomach, situated near the lesser curvature and midway between the pylorus and esophagus. At base of ulcer was an erosion of a large branch of the gastric artery. Near the open ulcer were 2 small cicatrices. The anastomosis admitted the passage of middle finger.
J. J. F. Mar., 1903. 9	M.		"Indigestion for years." Two days before entrance had a sharp epigastric pain; and later vomited coffee-ground material. Vomiting continued at entrance. There was extreme pallor, a retracted abdomen with epigastric tenderness and a thready pulse at 190.	Exploration of stomach through incision in anterior wall showed only blood clots. Two other incisions at cardiac end failed to show any ulceration. Incisions sutured.	Died 3 hours after operation.	Did not rally after operation. Autopsy showed a small ulcer with a cicatricial base, located at the pylorus. At the center of the indurated base was a bright red spot which was evidently the source of the hemorrhage.
A. R. F. Nov. 1903. 10	M.	39	"Stomach trouble" for 2 years. For 5 weeks epigastric pain and occasional vomiting, during which time he had lost much weight and strength. For 2 days stools had been tarry and offensive, and he had grown weaker. Five hours before entrance there was a sudden collapse. At entrance the skin was grayish; expression anxious; pulse of 100, regular and of fair strength. Tenderness and spasm in epigastrium.	High left rectus incision. Ulcer 2.5 cm. in diameter, situated 10 cm. from the pylorus on the lesser curvature. Ulcer evidently chronic, having a cicatricial base. At the center of the base was an eroded vein, which was plugged by a clot. Excision of ulcer and suture of stomach wall.	Died on 3d day after operation.	For 36 hours did well. Then followed a rapidly rising pulse, restlessness and marked thirst. Salt infusions, gelatin and adrenalin without effect. Autopsy. Stomach free from blood, but considerable old blood in the intestines. Inhalation pneumonia, which was probably the cause of death.

V. GENERAL CONCLUSIONS.

(1) The results of the operations in benignant disease of the stomach at the Massachusetts General Hospital and the Boston City Hospital between Jan. 1, 1898, and Jan. 1, 1904, are as follows:

	Number of Cases	*Deaths*	*Well*	*Rel'd*	*Not Rel'd*	*Secondary Operations*
Chronic ulcers	21	5	7	4	5	8
Pyloric obstruction	21	5	9	3	4	2
Acute dilatation	1	1				
Perforation	18	13	5			2
Hemorrhage	10	10				1
Total	71	34	21	7	9	13

(2) Surgical intervention in gastric hemorrhage should be considered even before it is urgent and the surgeon should jointly with the physician

watch the course of the patient. Cases of gastric hemorrhage entering the accident room should be seen as a rule by a physician as well as a surgeon. Operations upon females under thirty years of age should be most conservatively advised, since death under medical treatment is rare. This generalization, however, should not unduly influence consultants in a case of repeated hemorrhages threatening life, even in a patient below this age. Time should not be lost during an operation in seeking the bleeding point, but gastro-enterostomy should be performed.

(3) Mortality in operations for perforation of the stomach is chiefly dependent upon the length of time intervening between perforation and operation and the virulence of the infection. To lessen the mortality, house officers should report suspected cases simultaneously to the physician and surgeon on duty, or their substitutes, and should obtain permission for a possible operation from the patient or friends.

(4) Patients with chronic ulcers of the stomach or strictures of the pylorus should be jointly watched by the physician and surgeon. The surgeon should know the patient before being compelled to operate. Postponement of operation after it is indicated is dangerous, owing to the possibility of hemorrhage, perforation and exhaustion.

(5) Errors in surgical technique occurred, which in subsequent operations will presumably be avoided. Methods of operation were chosen which in the light of the experience of to-day would be considered unsuitable. Together these classes of cases account for about half of the deaths.

(6) The seventy-one cases were operated upon by twenty-five different surgeons — an average of one case to each surgeon in twenty-five months. It is reasonable to conclude that the mortality would have been less if each surgeon had had more experience.

THE UNION OF THE TEACHINGS IN CYSTOSCOPY AND MICROSCOPY.

BY FRANK M. JOHNSON, M.D., BOSTON.

AN adage of an earlier time still rings with the same truth and its forcible meaning to-day. It was then the thought had birth that "in union there is strength." Thus from a medical standpoint might its application be converted to carry out the peculiar characteristics of these two adjuvants in our investigation of the diseases of the bladder and the kidneys. It is not the intention at this time to enter into the minute details of the methods used, or descriptions of various instruments, but rather to bring perhaps more forcibly to your attention and consideration the value of suggestions to be gained when in harmony the microscope and cystoscope can give to us more clean-cut and definite knowledge. Before instrumental interference is demanded or warranted, the wise procedure is to obtain a complete record from an exhaustive chemical and microscopical analysis of a specimen of urine. By this step a diagnosis is obtainable that will most likely approximate the conditions to be met with.

From the number, condition and appearance of the epithelia present, the presence or absence of casts, mucus, red blood corpuscles, pus corpuscles, connective tissue shreds and the varied forms of crystalline and amorphous sediments, — all these with the data of clinical history, in a certain case, will repay by the value of the deductions that are now far less difficult to surmise.

If a doubt might remain, it is then that the cystoscope will readily prove or disprove the microscopic findings. The tiny brilliant electric light, in conjunction with delicate lenses, gives to the observer vivid pictures and often clears up mysteries that were perplexing.

A growth is discovered that before gave no symptoms or signs of its existence. A clever instrument, lately devised by Dr. Follen Cabot of New York, enables an operator to secure a small piece of such a growth, and then our microscope will reveal its nature, or a fragment of a calculus is caught up, and its composition soon determined. Again, with angular or straight observation telescopes, all parts of the bladder can be viewed. Various grades of inflammatory origin can be seen and exact conditions realized.

Now perhaps it is fairly said that the microscope first gives permission, and then may demand the cystoscope as its aide-de-camp. May the day come, and that quickly, when such examinations as have been noted play their important parts in our routine practice; may our microscope receive the consideration that its teachings merit! No doubt a human life cannot nor will not last long enough to make the master of any person who may attempt to solve all the problems, all the riddles and all the kaleidoscopic transformations that lie within the minute drop — under the fragile crystal. Errors arise due more often to the lack of complete understanding on the part of the observer than to any fault that could possibly escape detection in a finely made instrument. Each and every object must meet with recognition, and relative values of the more important elements must have our careful consideration. The surgeon whose time is absorbed with many operations, the general practitioner who has no moments he may call his own, yes, even the successful follower of some special subject, is forced to rely upon some one else and accept his conclusions. The necessity of true, impartial, microscopic findings, however, will still constitute a factor of mighty value.

This same thought can apply again to the cystoscopic revelations. Both these measures require time, patience and a long experience. Can one in a pardonable enthusiasm overestimate their true worth? At the present time the most important rôle played by the microscope and cystoscope is in the examination of the kidneys. With the catheterization through the

ureters, and the microscopical examinations of the separate urines, a vista of new thought is opened, whose field of usefulness is large and wide and whose possibilities are almost beyond comprehension. Here will it be found, that before a kidney is removed the surgeon must know the absolute conditions of both kidneys, or perhaps the location of a calculus or of growth in the bladder and its character. A very few out of the many doubtful phases may be dispelled by these methods of research from a surgical aspect. For a moment then, only lightly touching this phase, we turn to a large number of patients who apply for medicinal treatment for alleviation of their pains, distress and exhausted nervous conditions. When the true realization has not been granted to the physician, who certainly has done everything in his power, yet when medicinal remedial measures have been without avail in either giving nature a chance to cure, or of completely alleviating the stubborn symptoms and their sequelæ — let it be said frankly and squarely that lavage of the pelves of the kidneys with appropriate medicated solutions given carefully and each change and effect noticed will, in the majority of our cases, either eradicate or certainly will ameliorate the disturbing influences created by a chronic pyelitis, or a pyelo-nephritis or cirrhosis, those of lithemia or an irritative oxaluria; these alone being simple examples of a thousand varied and complex conditions that may arise.

These few suggestions are offered with the hope that they will awaken a broader and keener interest, that they may appear worthy of deliberate consideration, and that each and every true student, who has devoted his life to a beloved cause, can, if he will, find helpful aid and gain a clearer vision from the keener sense of a better understanding through this union of thought in the teaching of these two most valuable and, may it be said, inseparable companions, — the microscope and cystoscope.

Clinical Department.

A CASE OF UNIRADICULAR BRACHIAL PALSY AFFECTING THE FIFTH CERVICAL NERVE.

BY JOHN E. DONLEY, M.D., PROVIDENCE.

The following case, which was referred to me by Dr. Frank H. Jackson, would seem to be worthy of record, since it probably represents a very rare palsy of the brachial plexus:

Miss C., a young woman of twenty, a book-binder by occupation, came under observation complaining of disability and of some pain in her left upper arm. Her family history is unimportant, except for the fact that her father suffers frequently from attacks of severe articular rheumatism. She herself has always enjoyed good health with the exception of an attack of malaria of one week's duration, five years ago, and her appearance in general is that of a well-nourished and healthy girl. On Easter Sunday, ten weeks before coming under observation, having exchanged heavy for light clothing, she took a long walk, and upon returning home complained of feeling very cold. On Monday a sharp pain appeared in her left shoulder and neck, and by Tuesday it had become more severe, and was especially intense at night. By Wednesday it had extended as low as the elbow, and the arm was somewhat swollen from the shoulder to the elbow-joint. On Friday the pain had involved the forearm and fingers, and at the same time the right arm became swollen and painful from the shoulder to the elbow, this condition persisting for a week, when the pain and swelling in the right arm and left forearm disappeared rapidly and have not returned. A week after the beginning of the trouble she put her arm in a sling, in which she carried it for three weeks, and only at the end of this time was it noticed that there was inability to flex the forearm or to move the upper arm, although she cannot tell how long this disability had existed before she became aware of it. From the first she received constitutional treatment for rheumatism, and at the end of eight weeks came under the writer's attention, when the signs of disease were as follows: There was paralysis with atrophy of the left supra- and infra-spinati, teres minor, deltoid, serratus magnus, both rhomboids and pectoralis major. These muscles did not react to faradism and gave quantitative changes to the galvanic current, contracting sluggishly to strong currents. The left biceps was perhaps a little weaker than the right, but showed no alteration to electrical stimulation. The atrophy in the deltoid, spinati, teres minor and rhomboids was severe. The scapula was winged, its lower angle approaching the vertebral column and its upper part being directed outward. The whole scapula was elevated. The acromion was uncovered and the head of the humerus had dropped from the glenoid cavity, an inch intervening between the acromion and the head of the bone. There were some thickening and adhesions about the joint, passive abduction and external rotation being partly restricted. There was no fluid in the joint. Voluntary abduction, external and internal rotation were absolutely impossible. The nerve trunks were not tender in the arm, but firm pressure over the plexus above the clavicle gave tenderness. There had never at any time been tingling, numbness or other paresthesia, nor had there been herpes zoster or any variety of skin eruption. Sensation was everywhere normal except over the lower deltoid region, where there was some blunting of sensibility to pain, tactile and thermal stimuli, the defect, however, not being marked. No affection of the brachialis anticus, supinator longus, triceps, subscapulasis or diaphragm could be discovered. There was no sign of disease in heart, lungs or other viscera.

Although we are acquainted with many cases of paralysis affecting several of the peripheral or proximal nerves, or as in the palsies of Erb and Klumpke, combined cords of the brachial plexus, the number of recorded cases in which the lesion has been limited to the individual spinal nerves is small, and the literature very meager.

Buzzard, in a recent article in "Brain," remarks upon the infrequency with which uniradicular palsies are mentioned, even in the extensive monographs upon the subject, and he quotes from Duval and Guillain, Secretan and others, whose only reference to the subject consists in the statement that uniradicular palsies of the brachial plexus are exceedingly rare. In the same contribution, Buzzard reports six cases,

three of them suggesting a lesion of the first dorsal nerve, two of them a lesion of the fifth cervical nerve, and one a lesion of both these nerves, and he suggests that this may be a coincidence, or it may point to a special susceptibility on the part of the lowest and highest roots of the brachial plexus. Wolfstein has recently recorded a case in which the lesion appeared to be limited to the first thoracic nerve, and our own case points to an involvement of the fifth cervical nerve, so that the observation of Buzzard as to the greater susceptibility of these nerves would seem to receive some confirmation.

The distribution of the paralysis in our case is interesting as affording evidence of the motor innervation from the fifth cervical root. It involved temporarily the biceps, and permanently the deltoid, teres minor, serratus magnus, both spinati, the rhomboids and the pectoralis major. There was no evidence of any affection of the spinal cord, no stiffness of the neck and no change in the neck muscles. The tenderness over the brachial plexus points to peripheral trouble, so that if we exclude multiple foci in several nerves, the site of the lesion must be as repre-

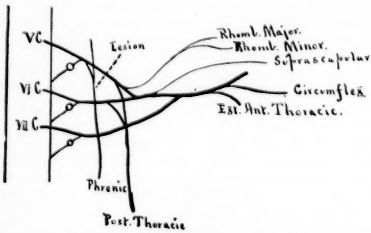

Diagram (after Buzzard). Illustrating position of lesion affecting fifth cervical nerve.

sented in the accompanying diagram. The nerves supplying in part the serratus magnus, the levator scapulæ and the rhomboids arise from the fifth cervical nerve, as it lies between the scalene muscles, and in order to account for the paresis in our case the situation of the morbid process must have been in that part of the root proximal from the origin of these nerves.

It is interesting to note that at the time of the examination, the levator scapulæ was not involved. The muscles affected support the observations of Herringham, which the writer has confirmed in the case of the suprascapular and circumflex nerves and the outer head of the median. Herringham concludes from his dissections as follows: (1) It is usually at the junction of the fifth and sixth nerves that the suprascapular nerve is given off, but it is not uncommon to find it springing from the fifth before the junction is made. (2) The sixth, therefore, exercises sometimes an extremely small influence and sometimes none at all over the spinati. (3) It appears that the pectoralis major does not usually receive from the fifth. (4) The biceps is supplied by the fifth and sixth seven times out of eight. (5) Thirty-one dissections showed no exceptions to the rule that the fifth does not enter into the outer head of the median. (6) The circumflex comes from the fifth and sixth; in six cases from the fifth alone; sixth branch often very small. (7) The teres minor is always supplied by the fifth alone. (8) The supinator longus and brevis are usually supplied by the sixth; the fifth is not always excluded. The muscles paralyzed in our patient appear to show that in this instance, at any rate, the fifth nerve gives motor innervation to the pectoralis major and a partial nerve supply to the biceps, for it will be remembered the biceps was paralyzed for at least a week, when it promptly recovered.

The sensory loss in the circumflex area was not unexpected, but the subjective sensations, or rather lack of them, are interesting and important, and apparently, as suggested by Buzzard, have some diagnostic value. Buzzard was impressed by the fact that in not one of his patients was there any sensation of numbness in the affected region, and not until it was pointed out to him was the patient aware of his sensory loss. Wolfstein had the same experience with his patient, and in my own case careful inquiry directed to this point failed to elicit any subjective sensation other than that of pain. The patient was somewhat surprised when it was demonstrated to her that there was a hypnesthetic area over the deltoid skin. It is quite possible, therefore, that this absence of subjective sensation of tingling and numbness may prove to be a valuable sign in distinguishing root from peripheral nerve lesions.

As to the etiology and pathology underlying the symptom complex in these cases, we are unable at the present time to advance beyond speculation. The term "neuritis" which has been applied to indiscriminate nerve lesions is a legacy from former days, when nervous pathology was oftentimes neither accurate nor careful of distinctions. We are beginning to understand that in the case of the spinal cord and peripheral nerves, as well as in the affections of the brain, we must distinguish between true inflammatory processes and those others, probably more frequent, of vascular origin. The work of Williamson, Singer and others has demonstrated that in many cases of what was formerly called "myelitis," the lesion is really a thrombosis due to disease of spinal blood vessels; and while as yet we have not the confirmation of the microscope for our hypotheses, it seems reasonable to assume by analogy that the same distinction should be made in diseases of the peripheral nerves. In our own case the symptoms are suggestive of a vascular foundation for the trouble, particularly the rapidity with which the pain and swelling disappeared from the right arm and the left forearm, this taking place during one night. And furthermore, the limitation of the lesion to a restricted area of one nerve seems to

favor a primary vascular process as against an inflammation, for in the latter case the nerve involvement would probably have been more extensive.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION FOR SURGERY.

E. A. CODMAN, M.D., SECRETARY.

A MEETING of this section was held on Jan. 6, 1904, DR. F. B. HARRINGTON, in the chair.

The subject for discussion was

EARLY OPERATION IN DISEASES OF THE STOMACH

with especial reference to the following questions which were announced on the call for the meeting:

How often is persistent stasis of the stomach contents due to a purely functional condition?

Should exploration be advised as a routine in cases of marked stasis of the stomach contents?

Comparative results of medical and surgical treatment in cases of stasis.

DR. F. B. HARRINGTON: The object of this meeting is not a discussion of gastric surgery in general but of certain non-cancerous conditions of the stomach, such as gastric ulcer, stricture of pylorus, hemorrhage, dilatation of the stomach, etc.

We live in a medical community which takes pride in its advanced position in medical knowledge, and yet in the West, Mayo has operated on nearly 150 cases of benign disease of the stomach, doing gastric anastomosis with a mortality of 6%, and in Leeds, Moynihan has just reported 100 gastro-enterostomies for gastric ulcer with two deaths. In the well-known paper on "Gastric Ulcer at the Massachusetts General Hospital, 1888 and 1898," Greenough and Joslin say: "The mortality of 8% and the failure of medical treatment to effect lasting cure in 60% of the patients indicates the need of surgical intervention in other than emergency cases of this disease." Dr. Munro ("The Surgical Treatment of Gastric Ulcer") says: "In cases of pyloric obstruction, we have a purely mechanical problem with which to deal. No amount of medicine can overcome this condition; no amount of argument by the internist can convince the surgeon that such cases are best treated medically.". Mayo says ("Operations on the Stomach"): "The hope of the future lies in early exploratory incision, and the necessity for this depends upon clinical observation rather than laboratory methods, which too often only become valuable when the extent of the disease is beyond cure. Given a patient of middle or later life who begins to lose flesh and appetite and suffer from indigestion without apparent cause, the possibility of cancer should be considered; and if the source of the symptoms cannot be shown within a few weeks, the situation should be explained to the patient and the choice between exploration and procrastination allowed him."

The mortality from gastric surgery will always be high in advanced cases of malignant disease and in cases of non-malignant disease in greatly enfeebled subjects when operation is done as a last resort. Much of the operating in this community has been of this latter sort, and the results must necessarily be less encouraging than operations on more favorable subjects.

A mortality chart prepared by DRS. F. T. MURPHY, G. O. CLARK and F. B. LUND was then exhibited and explained. This chart compared the reported statistics of Mayo with the actual mortality of a similar series of statistics compiled from all the stomach cases operated on at the Massachusetts General and Boston City Hospitals. It had been intended that Dr. Murphy should have given a more detailed explanation of this chart, but owing to his absence the explanation was made by Dr. Codman, who said that the object in thus contrasting the immediate results of the stomach cases done in Boston with those of Mayo, Moynihan and others, was to arouse more general interest in gastric surgery. Although in the cases of the above-mentioned surgeons the results might be expected to be better by a considerable per cent from the mere personal skill and experience of the operator, yet he thought that the main reason for the relative greatness of our mortality was due to the character of the cases which came to the operating table. Even considering the fact that the operations in the Boston hospitals were done by a large number of relatively inexperienced operators, who each had but a few cases, and that the operations were in almost every case *last resort* operations, the mortality as shown by the chart was not so very great, except in the malignant cases. Even in the malignant cases for the five years ending with 1903, only seven of the eighteen gastro-enterostomies at the Massachusetts General Hospital died. One of these Dr. Codman operated on himself as an emergency on account of perforation of a malignant ulcer. The other six cases were in very advanced malignant disease and most of them had palpable tumors.

Owing to the discussion aroused by the meeting, Drs. Joslin, Lund and Murphy were interested enough to prepare a detailed paper[1] on the non-malignant stomach operations at both the larger hospitals in the last five years, with especial reference to the end results.

DR. F. PFAFF: Your secretary requested me to answer especially the second question on your program, — Should exploration be advised as a routine in cases of marked stasis of the stomach contents? To answer this question briefly I would say absolutely not before medical treatment has been tried to either relieve or cure the stasis of the stomach contents. Why should not an exploration be made in cases of marked stasis of the stomach contents? Stasis of stomach contents is always due to motor insufficiency of the muscular apparatus of the stomach. Motor insufficiency may be caused by many different factors which can be completely relieved, even after marked stasis of many years, by medical treatment. I say motor insufficiency is the general cause of all cases of stasis of the stomach contents. It may be due either to muscular relaxation of the muscular apparatus, the muscle becoming too weak to expel the stomach contents in normal condition at the normal time. The stomach at first is of normal size, but later, due to stagnation of food, we get permanent enlargement of the stomach. Muscular insufficiency may be further due to impossibility of the stomach contents to get out through a narrow orifice. In such cases the muscles of the stomach may be hypertrophied and yet insufficient. The cause may be either intragastric or outside of the stomach, as in cases of gallstones, adhesions, etc., but even in such cases we may sometimes be able, by medical treatment, to relieve the stasis, and not only get again normal expulsion of food contents, but the patient may also gain in weight. Very often we see stasis of the stomach contents due to general conditions — gluttony, malnutrition, pro-

[1] This paper forms the leading article in this number of the JOURNAL.

longed fever, etc., We find stasis of the stomach contents much oftener than is generally admitted. I make it a rule to always examine the motor power of the stomach, no matter what the condition complained of by the patient is — not so much stress to be laid on the chemical condition of the stomach contents as the motor sufficiency or insufficiency of the stomach.

The statement made by the authorities abroad to the effect that if one finds stomach contents present seven hours after a test meal the case is one of motor insufficiency does not apply to all of the cases seen here.

American people as a rule eat greater quantities of food than they do abroad, especially at night, the stomach naturally becomes accustomed to a relatively greater amount of work, and consequently if you give them a light test meal subsequent examination fails to reveal evidences of motor insufficiency.

I have found by experience in treating my patients here, that the best methods to use in giving the test meal is to have the patient eat a dinner at night and then wash out the stomach the next morning, some twelve hours later. If then there is any food present, you may be sure the case is one of motor insufficiency.

My main object is to find out the cause of the stasis, and according to the cause I arrange the treatment. First of all a suitable diet is to be given. Lavage is only indicated in very marked stasis of the stomach contents, light stasis we can get rid of with diet. The more intelligent the patient, the better the results. If after months and months of trying the patient has not gained in weight, and the stasis has not decreased, then surgical treatment may be resorted to. First of all, to my mind, medical treatment, then surgical. Abroad operations are done much less often now than fifteen years ago.

DR. M. H. RICHARDSON: I have little that is new to say on this interesting subject. I was impressed early by the great anatomical advantages of the stomach for successful surgical operation, especially by the splendid results of even the most extensive surgical operations upon healthy individuals. By *healthy individuals* I mean those whose general condition is favorable for operations upon a purely limited disease. I should have said in prefacing these remarks that I have nothing to say with reference to the first question. With regard to the second question, I think nothing can be added to what Dr. Pfaff has already said. As to the indications for early operations, my experience is that if the patient is in good general condition the mortality from the most extensive surgical operations is small; while, if in a poor general condition, the mortality, even from a comparatively trivial operation, is great. In the former case the results are splendid; in the latter, deplorable.

I have to-day looked over in my card catalogue the collection of stomach cases that I have had in the last fifteen years. A brief glance at these cases shows, first, that the mortality in operations upon the stomach is caused by the patient's poor general condition, and not by the operation. The mortality in the tabulation before us, as all will admit who have seen the cases, has been dependent directly upon the advanced cachexia at the time of operation. In gastric cancer especially, the mortality from simple exploration with the finger has been in my own experience considerable. In many cases deaths have been recorded as caused by exploration when the patients would have died in a very short time if they had not been operated upon at all. The mortality in these exploratory operations for hopeless cancer shows nothing at all except that in advanced cachexia it is necessarily great. To compare in this table, or in my own cases, the dangers of operations upon a stomach extensively diseased with cancer with the dangers of resecting the pylorus in an individual in comparatively good health suffering from a benign stenosis of the pylorus is unfair. The latter has been a very successful operation in my own experience, even in cases in which we have made a complete pylorectomy. I have not the least doubt that if we could take healthy individuals under fifty or sixty — patients whom we describe as favorable for operation — the mortality, even of resection of the pylorus or of the stomach itself, would be very encouraging. My own experience bears out this statement. Many explorations for extensive cancer, as I have said, are fatal, even if you do nothing beyond making a simple incision. In resection of the pylorus for benign strictures from foreign bodies, corrosive poisons, etc., the mortality is small and the outlook most encouraging. The mortality after operations for other and rarer conditions, if the patient is in good condition, is small, even when the dissection is most extensive.

These remarks introduce the question: What are the early indications for operation? We should, I think, consider first the disease of the stomach which is perhaps the most common — cancer. I am convinced that, with the application of present knowledge and experience at the hands of men the most skilful in diagnosis of gastric diseases, seldom can the diagnosis of cancer of the stomach be made early enough for a permanently successful complete excision. I say this with profound respect for the skill of the most skillful. My conviction is that we must operate before the diagnosis can, from the nature of things, be positively made. The ultimate results in cancer of the stomach are bad enough even in cases which we discover accidentally during explorations for other lesions. All the patients with cancer of the stomach that I have operated upon are, I believe, dead, except one whom Dr. Joslin and Dr. Pfaff will remember, and another in whom I discovered the disease in exploring a gall bladder. When the diagnosis of cancer of the stomach is made by the discovery of a tumor, there is, in the great majority of cases, no use in operating at all. Indeed, in my experience, a perceptible tumor is almost a contra-indication for operation. The earliest indication for operation in cancer of the stomach is a strong suspicion of that disease. The mortality from exploration itself in that early stage is extremely small, although there always must be some mortality in abdominal exploration — however brief.

With reference to the indications for operation, in patients whose symptoms are comparatively trivial but prolonged and obstinate, I am convinced that the earliest indication for surgical intervention in this class of case is the failure of medical treatment under the direction of skillful physicians.

This subject is extremely interesting to all surgeons. While we should strive to be in the front rank in the surgical treatment of gastric diseases, there should be, I think, on the part of some at least, a restraining conservatism rather than a frequent resort to such operations as gastro-enterostomy for trivial symptoms. We should know, definitely and unmistakably, the permanent results in a large number of cases in which this operation has been performed for gastric atony, *e. g.*, as compared with medical and palliative treatment of these cases.

DR. A. T. CABOT said that he understood the term "persistent stasis" to mean a stasis which is not relieved by medical treatment, or if so relieved soon recurs. Defining "persistent stasis" in this way, he felt that it was rarely a purely functional condition. When this stasis is so pronounced that the stomach

fills up and is obliged to empty itself by vomiting once or twice a day, it is evident that some mechanical condition or obstruction must exist, and such a stomach should be operated upon at once.

When the stasis is less pronounced than this, of course, medical treatment may be given a somewhat longer trial, but if it constantly fails to afford permanent relief, surgery should not be too long delayed.

He said that he should like to hear from some of the medical practitioners as to the permanency of results that they obtained by their treatment of these cases of stasis. What, in short, they expected to accomplish, failing in which, they are prepared to turn their patients over to the surgeon. He said that his feeling was that the surgical statistics in this neighborhood were bad because the cases brought to the surgeon had been unfavorable. That it seemed to him that if the medical men throughout the community could be convinced that surgery does offer sure relief in these cases, and would learn to recognize earlier the cases in which medical treatment is not likely to prove successful, he was sure that many more surgical successes would be accomplished in gastric cases.

Dr. J. T. Bottomly: (1) How often is persistent stasis of the stomach contents due to a purely functional condition?

In the fairly large experience of my colleague, Dr. Munro, and in my own brief experience in stomach cases, we have yet to open an abdomen as an exploratory measure in cases with symptoms of gastric stasis and find no pathological or mechanical cause for the trouble. Perhaps, I should modify that statement a little and say that, if we have found no cause for the symptoms, drainage of the stomach by gastro-enterostomy has in the vast majority of cases given such satisfaction that we could onlly conclude that some cause other than a functional one was at the bottom of the trouble.

(2) Should exploration be advised as a routine in cases of marked stasis of the stomach contents?

It is our belief that exploration should be thought of not only as a routine but as an *early* routine measure. I want to lay a special stress on "early" as a matter of justice not only to the surgeon, but what is most important, to the patient. Given a surgeon familiar with the technique an exploratory operation of such a nature in a patient in good, even in fair, condition has but little danger attached to it. This holds true, even if a gastro-enterostomy is done. But this presupposes a patient in at least fair condition, and does not hold good for patients who come to the surgeon in a half-starved, weakened condition.

Moreover, our operations have often disclosed a state of affairs that no man with our present means of obtaining knowledge could possibly foretell, — such as dilated or sagging stomachs due to adhesions about the pylorus, about the duodenum, about a chronically inflamed gall bladder, etc., — cases in which one could not possibly foretell the cause of the stasis, cases in which no amount of medical treatment could have any lasting effect, but in which surgical measures can and do afford not only marked but immediate relief.

(3) Results.

Surgery of the stomach is still comparatively young. We do not get brilliant results in all cases. It is only fair to say that we get good, most satisfactory results when we get the cases in fairly good condition. Most of the deaths in stomach surgery are caused by the condition of the patient when he gets to the surgeon, and not to the operation itself. Statistics do not always tell the whole story. We must know conditions before we can pass judgment on the merits of a given form of treatment. Both sides should be fair in this matter. What we are looking for is the good of the patient; this is the common ground on which both sides stand. We must admit with Mayo that there is certainly a time in the history of cases of stomach trouble when medical treatment is no longer useful. When does that time come? In all justice to everybody it comes before the patient has reached a state of anemia and weakness in which he is in no condition to undergo what might otherwise be a simple operation.

There is much truth in what Murphy says, and I want to quote a few words of his: "On the basis of frequency with which surgical diseases of the stomach are brought to the surgeon's notice, we may divide them into: (*a*) gastric carcinoma; (*b*) gastric ulcer; (*c*) pyloric obstruction; (*d*) pyloric retention; (*e*) gastroduodenal or pyloroduodenal lesions.

"If surgery is to accomplish for the stomach all that it is capable of, the frequency with which surgeons deal with the stomach must be for lesions in substantially the reverse order, except in the class of gastroduodenal disease, — *i. e.*, to obtain the greatest results from a prophylactic as well as therapeutic standpoint. The order of frequency with which the surgeon should be consulted must be — (1) pyloric retention; (2) pyloric obstruction; (3) gastric ulcer; (4) gastric carcinoma; (5) gastro-duodenal lesions." We must, in other words, get at cases early. Improvements in technique will probably not aid us greatly. The gain must come through earlier operation. Mayo Robson reports 101 cases of posterior gastro-enterostomy with 3.9% mortality and 21 cases of pyloroplasty without a death. Most of his deaths were due primarily to the poor condition of the patient at the time of operation.

STATISTICS.

The following is a condensed table of the operations performed for gastric troubles by Dr. Munro and myself. Most of them were done at the Carney Hospital and the great majority of them by Dr. Munro. By "recovery" in the table, recovery from the operation only is meant. It does not always signify permanent recovery.

	Number	*Recovery*	*Death*
Perforating ulcer	6	3	3
Pyloroplasty	1	1	
Pylorectomy	1		1
Jejunostomy	2	2	
Gastrectomy (partial)	3	2	1
Penetrating wounds	2	1	1
Gastrostomy	4	4	
Gastrotomy	1	1	
Gastroduodenostomy	2	1	1
Gastro-enterostomy	45	38	7
Shortening gastrohepatic ligament	3	3	
Exploratory	9	8	1

Dr. M. P. Smithwick: If six hours after the heaviest of the three meals the stomach of a well-fed person isn't empty, it is slow-acting. If after the same period it cannot pass onward breakfast or lunch, there is stasis. If it isn't empty after the twelve or more hours before the morning meal, there is marked stasis.

In the dilatable, atonic stomach, so often the result of nervous exhaustion, food may be present constantly from breakfast until the evening meal, but not in any great amount before breakfast, unless there is considerable dilatation or marked ptosis.

Persistent, marked stasis is not often due to a purely functional condition, and justifies exploration. If, in the absence of any condition demanding further operation it is decided not to treat the motor insuf-

ficiency surgically, the confidence gained by exact knowledge is worth the risk from exploration.

Unsuspected conditions unsuited for medical treatment may be found, or conditions, like ulcer, requiring special precautions if treated medically. In some of these cases stasis may be the only striking symptom. The great variation in the clinical picture presented by the same condition in different cases necessarily renders diagnosis difficult and uncertain. Uncertain diagnosis means inappropriate treatment and perhaps unnecessary risk. Early exploration when necessary for diagnosis is conservative. The possible disadvantage of operations which, like gastro-enterostomy cause permanent alteration of the digestive tract, compel us to look beyond the mortality statistics. If medical treatment is available and promises ultimate ability to take enough food for proper nourishment, surgical interference is inadvisable, but we have no right by withholding surgical aid to make hopeless invalids of those who cannot be properly nourished without operation.

In cases of persistent stasis so marked that the stomach must empty itself largely by vomiting, immediate operation should be urged. No case of stasis should die of starvation.

DR. C. L. SCUDDER: I have been seeing a number of cases of gastro-enterostomy recently, and have been interested in them not only as bits of surgical procedure, but because there were about the stomach in almost all of these cases lesions which the physician did not recognize previous to operation as causative of the symptoms. When these lesions have been removed or relieved by operation, the symptoms have disappeared.

The cases of so-called chronic gastritis, sour stomach, chronic indigestion, biliousness, those general symptoms in which the physician may find no distinct physical signs, no great diminution or increase in HCl, no marked stasis of stomach contents, and in which the percussion may not determine that the stomach is dilated or that there is a gastroptosis, in those cases there will be found certain physical conditions which are amenable to surgical interference. It is in cases of this kind that Mayo is operating. In the group of cases I have been watching this winter there were adhesions about the pylorus or posterior surface of the stomach or the pylorus would not quite admit the finger tip; there was a dilatation of the stomach or there was a falling down of the stomach, sometimes not detected previous to the operation. It seems to me that the physical examination of such patients does not determine the condition present; that the early operation discloses a living pathology which is defining more and more proper surgical procedure.

DR. J. G. MUMFORD: In this investigation [2] we are after facts regarding the results of methods of treatment. A considerable number of cases treated *surgically* have been tabulated, with what results as regards the cure of disease and on mortality you are more or less aware. On the other hand, so far as I have been able to learn, satisfactory tables of *medical* treatment are not accesssible.

The discussion to-night centers around the question of stasis, which is usually associated with and dependent upon obstruction with dilatation.

I am at present engaged in a study of digestive disorders, for another purpose than to present it at this meeting, and my investigations are still far from complete; so that what I may say here must be taken in a qualified sense only, but such as they are the apparent facts are suggestive.

I found recorded in the clinical catalogue at the Massachusetts General Hospital 122 *medical* cases listed as "gastric dilatation"; no other diagnosis being made, probably because definite diagnosis in these cases was impossible; the presumption, of course, being that the dilatation was due to pyloric obstruction, malignant or non-malignant, though some few were called "atonic," and in very many of the cases, with our better knowledge of to-day, doubtless a correct diagnosis would now be made. It is an interesting fact that very many fewer cases of dilatation were reported fifteen years ago than to-day. These hospital cases cover fifteen years. In 1888 there was 1 case; in 1889 there was 1 case; in 1890 there were 3 cases, and so the annual number rises until 1895, when there were 17 cases. Then it sinks again until, in 1902, there were but 9 cases, and in the first six months of 1903 but 2 cases. These facts suggest that fifteen years ago gastric dilatation was infrequently recognized, and that in recent years the true cause of the dilatation has been ascertained and the cases recorded under a more accurate diagnosis than "dilatation" merely.

The average stay of these patients in the hospital was three weeks; the longest individual stay was eight months. It is my purpose to follow up all of these cases and ascertain their subsequent histories; but from the hospital records, at the time of discharge, we learn the following facts:

Of the 122 cases, 2 died in the hospital; 17 left the hospital without relief of symptoms; 98 had improvement or partial relief of symptoms; and only 5, or about 4%, were discharged symptomatically "well" (one of these returned for further treatment). Of these 122 cases, 87 or 71.3% were males; 35 or 28.6% were females.

These facts suggest the possibility, contrary to the usually accepted figures, that gastric ulcer, the commonest cause of pyloric obstruction, may be more frequent in males than previous statistics have stated.

The total number of cures at the time of discharge from the hospital is surprisingly small. It remains to be seen what improvement took place in the 98 cases who left the hospital, relieved only; what their length of life may have been, and what the cause of death.

DR. E. P. JOSLIN: About the medical results of these cases of stasis we know that some of them will improve, but many will not. I have only two stasis cases of marked severity which I have followed for two years or longer that are still all right. All the other cases I have had have been turned over to the surgeon.

[2] Owing to lack of time this was not read at the meeting.

Recent Literature.

A Practical Treatise on Medical Diagnosis for Students and Physicians. By JOHN H. MUSSER, M.D., Professor of Clinical Medicine, University of Pennsylvania; Physician to the Philadelphia and the Presbyterian Hospitals, etc., etc. Fifth edition, revised and enlarged. Illustrated with 395 wood cuts and 63 colored plates. Philadelphia and New York: Lea Brothers & Co. 1904.

We have already noticed Dr. Musser's Medical Diagnosis several times, and have only to add to words of previous commendation the statement that the present edition brings the book thoroughly abreast of the latest investigations in the field to which it is devoted.

The rapidly recurring editions testify to a deserved popularity among students and physicians.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 4, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 Bromfield Street, Boston, Mass.

THE ALLEGED PHYSICAL DEGENERATION OF THE ENGLISH NATION.

Notwithstanding the fact that the expectation of life has materially increased in England, as shown by the Registrar-general's figures, and by those of several medical officers of health in English towns,[1] it is still urged that the standard of health has deteriorated, and that the proportion of weakly persons surviving to adult life is greater than formerly. Newsholme has answered this statement in his comments upon the Brighton Life Table for 1881–90, and now after ten years more of experience in public health work, he replies to these propositions more definitely as follows:[2]

The principal reasons which have led so many to consider that the physical condition of the English population is deteriorating are the following:

1. The survival of a large number of adults, who would formerly have died of infectious, including tubercular, diseases, or of other diseases which now yield to medical and surgical skill.

2. The alleged increased stress of modern life.

3. The fact that the English population has become increasingly urban.

4. Industrial have in a large measure superseded agricultural occupations, and home industries have given place to those carried on in factories and workshops.

"1. It had been claimed that the operation of the law of the survival of the fittest had been impeded by the work of public hygiene, with results unfavorable to the health and vigor of adult life. This argument assumes that weakly children are more prone to attack by infectious diseases than robust children, an assumption which experience does not confirm. These diseases appear to attack the majority of children, weakly or robust, who are exposed to their infection. It might be reasonably expected, therefore, that with a decrease in the total deaths from infectious diseases, there would have been at least a corresponding decrease in the number of those who are left maimed by an attack of one of these diseases to survive to adult life. The weeding out of weakly lives, caused by the greater mortality among weakly children suffering from an infectious disease, is, in my opinion, counterbalanced by the greater number of children made weakly in former times by non-fatal attacks of an infectious disease.

"So far as consumption is concerned," Newsholme also says, "it may now be affirmed that in all probability any possible national deterioration caused by the survival of tubercular persons is at least counterbalanced by the improved health and physique of that large portion of the population who formerly would have become tubercular, but now remain free from this disease, as well as of the general mass of the population.

"2. *Stress of modern life.* — It is doubtful if increased strain exists in the community as a whole. Each adult, as he becomes year by year more deeply involved in the battle of life, comes to the conclusion that the general strain of life in the community is increasing, forgetting that the same causes operated as life advanced in previous generations. There is reason for thinking, with Dr. Pye-Smith, that much of the evil ascribed to 'over-pressure' is really due to over feeding and drinking.

"Assuming, however, that over-pressure exists in certain stations of life, *e. g.*, among city merchants, medical men, etc., it cannot be said to exist generally among professional men. Clergymen, lawyers and civil servants are, as classes, long-lived.

"Even assuming that over-pressure exists throughout the whole of the professional and mercantile classes, these do not form the mass of the community. The majority of the population belongs to the wage-earning classes, and the conditions of these classes will therefore necessarily have the greatest influence on the total result. Sir R. Giffin[3] shows that the wages of the agricultural laborer have increased, while his hours have decreased. In many trades, the workman gets from 50 to 100 per cent more wages than fifty years previously for 20 per cent less work. He sums up as follows: 'While the workman's wages have advanced, most articles he consumes have rather diminished in price, the change in wheat being especially remarkable, and significant of a complete revolution in the condition of the masses. The increased price in the case of one or two articles — particularly meat and house

[1] Annual reports of the Registrar-general of England and Wales. Similar figures for the population of Massachusetts were published in the Thirtieth Report of the State Board of Health for the year 1898, pp. 799–827.

[2] The second Brighton Life Table, based on the mortality experience of the ten years, 1891–1900, by Arthur Newsholme, M.D., Medical Officer of Health of Brighton, England.

[3] The progress of the working classes in the last half century. Inaugural address Royal Statistical Society.

rent — is insufficient to neutralize the general advantages which the workman has gained."

The author presents figures to show that the reduction of the death rate from phthisis in England has occurred almost *pari passu* with the reduction in the price of wheat. More than this, the English population has increased its standard of comfort and has become able to afford, not only more abundant, more varied and more wholesome food, but is also better clad and better housed than it has ever been in the past. It cannot, in short, be maintained, with any approximation to fact, that the majority of the English population live now under conditions of greater strain and stress, or that poverty is more prevalent than formerly.

In the tendency to rapid increase of urban populations, the author does not find evidence of national degeneracy of a decided character, for while the chances of acquiring infection are greater in town than they are in the country, this fact is balanced by the improved conditions under which indoor occupations are now conducted as compared with those of earlier periods.

The improvement in the expectation of life in recent years may be attributed to various causes; chiefly to the increased wealth and resulting comfort of the population, and the immense improvements in sanitation during the past thirty years.

Infant mortality has increased, not only in England but also in many American cities, and it is here that radical improvement may be attained by the introduction of measures designed to improve the methods and material used for infant feeding, since the artificial feeding of infants must be held responsible for a large share of infant mortality. Other means may be found in the establishment of day nurseries in large manufacturing districts and the improvement of sanitary conditions in the homes of the working classes.

BOSTON'S DEPENDENTS AND DELINQUENTS.

IN the appendix of the monthly bulletin of Boston's Statistics Department for April and May, 1904, are given certain interesting facts regarding the city's dependents and delinquents for the year 1903. The statement is made that these classes which are a public charge are so mixed that a division into those whom the city supports and those whom it only aids is extremely difficult. Aid, for example, is given to patients who pay, in the city and insane hospitals, but naturally such patients can in no sense be classed as paupers. Leaving such out of the account, there is a large class supported temporarily or permanently by the city. These include residents of pauper institutions, prisoners in city institutions, and Boston patients in the hospitals for consumptives, for epileptics and for dipsomaniacs. As a convenient classification those persons who received aid from the city or were supported by it for the whole or a part of 1903 are divided into sick, poor and criminals, although naturally such discrimination cannot be absolutely maintained. Estimating the population of Boston, Dec. 1, 1903, as 606,566, it appears that 9,537 individuals were supported or aided by the city on that date. Of this latter number 6,767 were in charge of institutions and 2,770 were in the receipt of permanent aid from the Soldiers' Aid Department. The proportion borne by the various classes of persons aided in December to the general population is given as follows: "Total cared for, 20,877 or 3.44%; sick, 3,659 or .60%; poor, 13,994 or 2.31%; criminals, 3,224 or .53%. Of the sick, 1,667 or .27% of the total population were in hospitals for general diseases, and 1,982 or .33% in hospitals for brain diseases. Of the total number cared for in the month, 11,572 or 1.91% of the population had indoor and 9,305 or 1.53% outdoor relief. Over 50,000 out-patients — not included in our tables — received medical aid from the Boston City Hospital."

Such figures and statistics are certainly illuminating. It is well for us from time to time to realize how widely disseminated the charity work of a great city becomes as its various departments develop. Classification is naturally in such matters difficult and at times impossible. It is, nevertheless, desirable to appreciate the fact that very many of those classed as poor or dependent without other reason are actually sick and should, as our methods of classification become more exact, be so recognized. Particularly must we protest against the tendency to regard the chronically infirm as totally distinguished from the more acutely ill. The definition of disease should be formulated, and all persons falling under this category should be regarded by the city authorities as sick and should receive the privileges accorded to this class.

SUICIDE IN NEW YORK.

ACCORDING to the reports of the Health and Police Departments the present year is likely to break all records for the number of suicides com-

mitted in New York City. During the first six months of 1904 there were over 450 suicides, a number which indicates a rate for the year of 224 to the million of inhabitants, as against 215 in 1903, 187 in 1902, 206 in 1900, and 150 (in the older city of New York) in 1890. If the relative proportion of suicides in the first half of the year is continued in the second, there will be over 900 in 1904, as against 806 in 1903, 772 in 1902, and 743 in 1900. The number of persons who have attempted suicide unsuccessfully during the half year just ended shows a similar increase over 1903, the figures being 264 for the current half year, as against 231 for the same period last year. At the same time, the suicide rate in New York is still considerably below that in any of the large European cities. The steady and noticeable increase in the suicidal tendency is no doubt to be ascribed principally to the increasing density of the local population and the rapidly growing complexity of metropolitan life, with its constant influx of ignorant foreigners but poorly equipped for a new struggle for existence. Almost two thirds of these suicides are among the foreign born. One fourth are Germans, and in commenting on this a prominent officer of the Health Department attributes it largely to the fact that, according to his observation, a considerable number of the Germans do not profess any established religion and have no particular scruples against taking their own lives. Also they are a "temperamental" people, highly sensitive to adversity. The French are also much addicted to suicide, but they form proportionately so small a part of the city's population that the total number of their suicides is small. The Irish, while constituting almost as large an element in the population as the Germans, do not furnish one third so many suicides. In the first quarter of 1904, 70 were natives of the United States, 58 of Germany, and 16 of Ireland. In the same period the principal means employed for self-destruction were as follows: Poison, 99 cases; shooting, 42; gas, 35; hanging, 20. Two fifths of those committing suicide now use carbolic acid, the reasons for this being assigned as its cheapness, its effectiveness and promptness, and the ease with which the drug can be obtained. A much larger proportion of men than women commit suicide, and the percentage of men appears to be increasing. During the past three years women have furnished only 27% of the suicides in New York, while in 1896 the percentage was over 39. Of those who attempt suicide but do not succeed a larger proportion are women, about two fifths of the attempted suicides being among females.

REPORT OF GOVERNMENT LABORATORIES IN MANILA.

We are glad to call attention to the second annual report of the superintendent of Government Laboratories in the Philippine Islands, taken from the fourth annual report of the Philippine Commission. The volume comprises 622 pages, and is most elaborately and attractively illustrated by numerous full-page half-tones. A glance at Dr. Freer's report discloses the increasing work which these laboratories are accomplishing in the determination of the innumerable questions presented by the diseases of the Philippines. Considering the very short time during which work of a scientific sort has been attempted, it is clear that a beginning has been made which must develop into most important results. Among other things which show the development of the work as a whole is the growth of the library which has been naturally somewhat retarded, owing to the difficulty of getting complete files of the various journals needed. At present the library boasts a large number of periodicals, including back numbers of the more important scientific publications in medicine and many fields of chemistry. In addition to these, subscriptions to foreign scientific and medical periodicals bring all the recent work of value within reach of the laboratories. Periodicals in the field of industrial chemistry and veterinary medicine are particularly needed for obvious reasons. The botanical laboratory, recently started, makes also a further demand on current literature. It is hoped that in the future this library, so auspiciously started, will be in general used by educational institutions throughout the Philippine Islands, and particularly will it be of advantage to native students who need the contact with modern scientific methods which such literature brings. As the report says, "An increasing number of Philippine students are now being educated in the United States, and it would indeed be a misfortune if upon returning to their native country they should be cut off from the literature which is most important in continuing their mental growth." It is quite impossible in the space at our command to do more than call attention to the contents of this really interesting volume. It will well repay a careful perusal by men engaged in widely diversified branches of scientific research.

MEDICAL NOTES.

HOSPITAL FOR CANCER IN PHILADELPHIA. — It is reported that plans have been formulated for the erection of a large hospital in Philadelphia to be devoted to the study of cancer and allied disease.

SUMMER COURSES IN PARIS. — It is announced that for the brief period from September 19 to October 1, various courses and practical medical demonstrations will be given at the Hôtel des Sociétés Savantes and in several hospital services in Paris. A large number of subjects are offered, and much of the teaching is done at certain of the well-known Paris hospitals.

SANATORIUM FOR TUBERCULOSIS IN DENVER. — A sanatorium for the treatment of tuberculosis, built by Mr. L. C. Phipps in memory of his mother, has recently been opened. The location is at a height of more than five thousand feet above sea level, with ample grounds. At present the institution is capable of accommodating one hundred. It is intended for curable cases.

PLAGUE IN TEHERAN. — It is reported that plague is active in Teheran, with a mortality reaching many hundreds daily. Europeans are said to be abandoning their property and leaving the region, and the Russian government has ordered the closing of the frontier to prevent the importation of the disease.

DEATH OF AN ENGLISH PHYSICIAN FROM PLAGUE. — The death from bubonic plague of Dr. Noel Unsworth, assistant inspector of the Sanitary Department of the Egyptian Government, is announced. Dr. Unsworth had previously been employed in Egypt during the cholera epidemic in 1902, and more recently was on plague duty in the Delta. His illness lasted but three days.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Aug. 3, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 30, scarlatina 11, typhoid fever 24, measles 16, smallpox 0.

QUARTERLY MEETING OF THE MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH. — The quarterly meeting of the Massachusetts Association of Boards of Health was held in Gallup's Island, Boston Harbor, July 28. Dr. Theobald Smith read a paper on the "Etiology of Leprosy," in which he discussed the history of the disease as well as our present knowledge of the subject. Dr. S. H. Durgin, Dr. Paul Carson, port physician, and Dr. H. W. Hill were some of those who took part in the discussion which followed on the general subject of leprosy.

PRACTICAL HEALTH EXHIBITION. — A practical exemplification of how to live has recently been given on the grounds of a club in one of the poorer sections of Boston. The exhibition was held under the auspices of various workers for the poor, among which the Association for the Relief and Control of Tuberculosis and the Health Education League were conspicuous. An attempt was made to demonstrate objectively various matters pertaining to health and proper methods of life. In one part of the grounds food was shown both in its natural and prepared states, and also what might be bought in the way of nutritious food for ten cents and lesser sums of money. An attempt was also made to illustrate certain chemical principles in relation to food. Elsewhere clothing for babies was illustrated graphically by two large dolls. The tuberculosis exhibit consisted of photographs of the State Sanatorium at Rutland and also the Sharon Sanatorium, with charts graphically representing the stages and spread of the disease. Outdoor treatment was illustrated by a tent and its appurtenances. Other exhibits were of a like practical nature, and addresses were also made by men prominent in charitable and hygienic work.

Obituary.

SIR JOHN SIMON, K.C.B., F.R.S., D.C.L., LL.D.

JOHN SIMON, born in 1816, became at the early age of twenty-four senior assistant surgeon at King's College Hospital, where, and at Greenwich, he studied for his degree. Two years later he wrote an essay which attracted wide attention, on "Observations regarding Medical Education." "His physiological essay on the "Thymus Gland," in 1847, gave him still more reputation, and after the publication of his "Aims and Philosophic Methods of Pathological Research" in 1847, he was appointed in the same year to the lectureship on General Pathology at St. Thomas's Hospital, where he endeared himself to the students as the personal friend and adviser of every one of the workers there.

He was one of a remarkable group of young men, including Edwin Chadwick, William Farr and the sanitary engineers, Lindley and Rawlinson, who early became interested in sanitary science, each of whose great usefulness measured nearly or quite half a century, four of whom received the coveted K.C.B., and to all of whom

civilization and humanity owe an immense debt of gratitude for the stupendous work which they did in general sanitary reform.

Farr's wonderful series of reports on vital statistics, begun in 1838 and continued for forty years, and Chadwick's masterpiece, a "Report on the Sanitary Condition of the Laboring Population of Great Britain," together with the wide-reaching legislation from 1837 to 1848, furnished the facts and the authority and gave the opportunity which Simon seized with that far-seeing wisdom, without which the laws might easily have remained without full effect.

He was health officer of the city of London from 1848 until 1855, when he accepted a similar position in the General Board of Health, the duties and powers of which in 1858 were transferred to the Lords of the Privy Council whose chief medical officer Simon became and remained until 1876. With his resignation the office lapsed. He was also, until 1876, Chief Medical Officer of the Local Government Board, created in 1871, in which he so thoroughly organized his department that it has continued in his methods ever since.

In the twenty-eight years of Simon's activity as a public officer his reports covered the whole range of public health with such clearness and force as to reach all classes. As edited and published by the Sanitary Institute of Great Britain in 1887 their eleven hundred pages are sufficient testimony to their paramount importance.

Simon was president of the Royal College of Surgeons in 1878 and of the Royal Society in 1879, and he held the highly-prized membership in the Atheneum Club. He was honorary member of various societies at home and abroad, and received honorary degrees from Oxford, Cambridge, Edinburgh, Munich and Dublin. He had been president of the Pathological Society, senior surgeon at St. Thomas's Hospital and member of the General Medical Council.

To great personal charm, Simon added a deep interest in people, great wisdom in selecting men for their work, marvelous perseverance and industry, surprising tact in dealing with the traditions and vested interests of an intensely conservative community, a delightful and forceful use of language which was both attractive and convincing, and a broad general culture.

After his resignation from active work at the age of sixty, he devoted himself partly to promoting measures of public utility in his chosen life-work, but more especially to art and general literature in which he had always been interested, and in parts of which, especially as regards the Orient, he became an authority.

His address before the International Medical Congress in 1881 on "Experiment as a Basis of Preventive Medicine" contained one of the strongest arguments in favor of vivisection.

Simon's generosity in giving full praise where it was due, to his assistants and to others, was a marked feature in his character, and enabled him to get the most efficient co-operation in all his wide and varied activities. In his "English Sanitary Institutions," a scholarly work of five hundred pages, published in 1900, he says that the modern demand for sanitary reform may be said to have begun in England in 1838, and that the successes which it gained in the next ten years were of so important a character that the story should be told in detail, adding, with characteristic self-effacement, "the story of the ten years is above all an account of the zealous labours of one eminent public servant, the present Sir Edwin Chadwick." During the succeeding quarter of a century Simon was easily the foremost power and influence in preventive medicine, and the monuments to his serviceable labors are to be found over Europe as well as throughout Great Britain and this country.

Miscellany.

OPERATION FOR PERFORATED GASTRIC ULCER.

According to the *Lancet*, the mortality after operation for perforation of a gastric ulcer appears to be diminishing. Mickulicz was the first to operate for this condition in 1880, but it was not till twelve years later, in 1892, that we have any record of a successful case, when Kriege sutured a perforation and the patient recovered. At first the mortality of recorded cases was very high, and in all probability the mortality of all cases treated by operation was still higher, for unsuccessful cases are never so readily recorded as the successful. Several factors have concurred in lowering the death-rate. Experience has taught us the best methods of operating, and practice has enabled us to operate more quickly, but probably the chief factor in lessening the mortality is the fact that cases are operated on at an earlier period after perforation, and as the length of the interval between the perforation and operation is the chief element in the prognosis, we must look upon any reduction of this interval as a potent agent in reducing the death-rate. Practitioners are more ready in invoking the aid of the surgeon now that they are acquainted with the value of early surgical treatment, and the public more readily submit to operation. It is not improbable that the mortality in hospital practice after operation for gastric perforation is less than in private practice, for in hospitals there is much less delay in preparing for an operation than is generally necessary when an operation has to be performed in a private house. In the present issue of the *Lancet* are recorded the notes of nine consecutive cases of operation for perforated gastric ulcer at St. George's Hospital. Eight of these patients recovered, and the only death occurred in a patient in whom perforation had probably taken place forty-eight hours previously, and who had had to travel about one hundred miles before operation. These results are excellent and reflect credit on the surgeons who performed the operations.

Deaths reported, 3,896; under five years of age, 1,680; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,621; acute lung diseases 206, consumption 389, scarlet fever 9, whooping cough 17, cerebrospinal meningitis 27, smallpox 1, erysipelas 4, puerperal fever 12, measles 17, typhoid fever 57, diarrheal diseases 1,045, diphtheria and croup 43.

From whooping cough, New York 5, Chicago 3, Philadelphia 2, Pittsburg 4, Lawrence 2, Melrose 1. From measles, New York 7, Chicago 2, Philadelphia 2, Baltimore 1, Pittsburg 1, Boston 1, Worcester 1, Lowell 2. From scarlet fever, New York 3, Chicago 1, Philadelphia 1, Baltimore 3, Pittsburg 1. From cerebrospinal meningitis, New York 22, Baltimore 1, Pittsburg 1, Worcester 1, Fall River 1, Marlborough 1. From erysipelas, New York 3, Chicago 1. From typhoid fever, New York 13, Chicago 9, Philadelphia 11, Baltimore 6, Pittsburg 11, Boston 4, Lowell 2, Quincy 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending July 9, the death-rate was 13.5. Deaths reported 3,948; acute diseases of the respiratory organs (London) 52, whooping cough 109, diphtheria 40, measles 182, smallpox 6, scarlet fever 32.

The death-rate ranged from 3.2 in Hornsey to 21.4 in Huddersfield; London 12.9, West Ham 12.8, Brighton 12.8, Southampton 12.1, Plymouth 16.0, Bristol 9.6, Leicester 10.7, Nottingham 13.2, Liverpool 18.2, Bolton 16.9, Manchester 17.9, Salford 16.2, Bradford 15.0, Leeds 14.8, Hull 13.8, Sheffield 13.7, Cardiff 7.7, Rhondda 14.5, Wigan 12.5, Merthyr Tydfil 15.8, Tottenham 6.9, Hanley 13.9.

METEOROLOGICAL RECORD.

For the week ending July 23, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING JULY 28, 1904.

GLENNAN, A. H., assistant surgeon-general. Granted leave of absence for fifteen days from August 1. July 22, 1904.

IRWIN, FAIRFAX, surgeon. Granted leave of absence for one month from August 15. July 26, 1904.

KALLOCH, P. C., surgeon. Granted leave of absence for twenty-two days from August 1. July 28, 1904.

MCINTOSH, W. P., surgeon. To assume temporary charge of Portland (Me.) Quarantine, in addition to other duties, during the absence on leave of Surgeon P. C. Kalloch. July 28, 1904.

GUITERAS, G. M., surgeon. Bureau letter of July 11, 1904, granting Surgeon Guiteras leave of absence for seven days from July 14, 1904, amended to read four days only. July 26, 1904.

MCMULLEN, JOHN, passed assistant surgeon. Granted leave of absence for one month from August 5. July 28, 1904.

GLOVER, M. W., assistant surgeon. Bureau telegram of July 13, granting Assistant Surgeon Glover leave of absence for seven days on account of sickness, amended to read five days from July 12. July 25, 1904.

WARD, W. K., assistant surgeon. To proceed to Bridgeton, Barbadoes, B. W. I., for duty in office of the United States Consul. July 12, 1904.

STILES, CH. W., zoologist. Detailed to represent Service at Sixth International Congress of Zoology at Berne, Switzerland, August 14–19. July 22, 1904.

SEAVEY, L. T., acting assistant surgeon. Granted leave of absence for fourteen days from August 8. July 27, 1904.

SMITH, EMMA F., medical inspectress. Granted leave of absence for thirty days from July 1. July 22, 1904.

BOARD CONVENED.

Board convened to meet at Washington, D. C., August 1, 1904, for the physical examination of an Officer of the Revenue Cutter Service, and an applicant for admission into said Service. Detail for the board: Assistant Surgeon General G. T. Vaughan, Chairman. Assistant Surgeon A. J. McLaughlin, Recorder.

PROMOTION.

L. C. SPANGLER, pharmacist of the third class, promoted to be pharmacist of the second class, effective May 28. July 25, 1904.

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING JULY 30, 1904.

F. M. FURLONG, passed assistant surgeon. Detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., August 5, and ordered to the "Chicago."

W. G. FARWELL, assistant surgeon. Ordered to the naval recruiting rendezvous, Boston, Mass.

J. F. MURPHY, assistant surgeon. Ordered to the "Hancock," temporarily.

G. H. BARBER, surgeon. Ordered to the "Hist," and to additional duty at the naval training station, Newport, R. I.

C. D. CATHER, assistant surgeon. Ordered to the naval hospital, New York, N. Y.

OPERATIONS ON THE STOMACH, WITH REPORT OF CASES.*

BY JOHN C. MUNRO, M.D., BOSTON,

From the Surgical Clinic, Carney Hospital, Boston, Mass.

THE bulk of the work reported here has been done within the last year by Dr. Bottomley and myself at the Carney Hospital; but I have included all of my own cases of operation upon the stomach from the very first, although the earlier operations were done with much less confidence in technic and with a bad prognosis in many instances. Frequently patients were turned over to surgical care after having tried everything in the way of internal medication, with the feeling in the medical attendant, the surgeon and the patient, that the knife was offered as a last resort. The earlier cases were, so to speak, filtered through medical hands. Latterly this has been done away with to a certain extent, because we are able to control our own clinic much more independently, and the patients are referred to us directly for the decision whether surgery can offer relief or not. If we did not have the convincing end results of surgeons of large experience, like Mayo, Mikulicz, Robson and others, I should hesitate strongly about reporting so many recent cases. We do know, however, from the experience of these surgeons that in cases of chronic ulcer, mechanical stasis and cancer, operation offers the best outlook at the minimum expense, and I feel confident that a good proportion of our temporary successes will abide, provided we have utilized properly the technic that has proven of benefit up to the present time. Time is necessary to establish the value of any method of treatment, and in the earlier applications over-enthusiasm and ill-trained judgment serve to weaken the virtues of any form of therapeutics. We must be willing to modify and change our surgical treatment of ulcers, dilatations and carcinomata of the stomach as the need is demonstrated. But meanwhile surgeons must continue sifting and rejecting, reporting and analyzing their failures as well as successes, just as they still do with their cases of appendicitis, gallstone, hypertrophied prostate, etc.

Last year, in a short plea made before the Medical Section of this Society, I begged that there should be a closer cooperation between the medical attendant and the surgeon, early in the progress of these cases; that for the patient's benefit, if for nothing else, he should be allowed to have an opinion from the surgical point of view. I am happy to state that I believe this plea has borne fruit in spite of the fact that our malignant cases still come too late for anything more than temporary relief.

I do not feel that surgery, or at least my surgery, has more than begun to solve the problem in the treatment of stomach diseases, and a perusal of my cases will convince you that there is much that has discouraged me throughout; but I believe a closer analysis will not place the odium for all our failures at the surgical door. In reporting the unsatisfactory results I have attempted as impartially as possible to fix the blame — if the term is not too harsh — where it belongs, whether on my own shoulders, or those of the reluctant medical attendant, or on the attitude of the laity in general towards seeking surgical relief. In spite of a case now and then that does not prove as satisfactory as we should like, both Dr. Bottomley and I feel that we are steadily nearing the point where we can judge what cases are to be discouraged as useless surgical risks and what cases can be assured of temporary or permanent relief. The risk from operation is lessening with experience and with selection of cases earlier in the course of the disease, until now I firmly believe that we can offer at least a gastro-enterostomy with no more risk of life than in the case of an interval appendix. I will frankly acknowledge that in several instances I have limited operation to a gastro-enterostomy, through timidity, rather than undertake a more radical procedure. The feeling of this community has been so strongly opposed to surgery of the stomach that it has seemed of the utmost importance, first of all, to establish firmly in the mind of the medical confrere that his stomach cases will not die under operation. If we can advance a little farther and establish in the mind of the general practitioner that the risk to life in any of the accepted types of operation is small enough to be disregarded when placed in the balance with the risks and the suffering that go with the so-called conservative treatment, we shall feel that the work has not been in vain. Moreover, the pathology of the various gastric lesions, as Mayo and others have pointed out, must be learned in the living at operation and not on the cadaver. All the time that we have been, so to speak, feeling our way, we have observed and noted the various conditions found at operation, hoping that eventually we can associate clinical symptoms with the operative findings.

It is a serious and embarrassing commentary that scarcely a single case of carcinoma in our series has sought, or been driven to seek, surgical aid until it was too late to attempt radical cure. There is no valid excuse nowadays with the clear-cut, splendid work of men like the surgeons named above, for the medical specialist to turn over his malignant cases, when far advanced in disease, with the apology that the laboratory failed to demonstrate a malignant process, at the time when an exploratory operation, as harmless as any major operation can be, would have definitely and accurately established a diagnosis.

It has been pathetic, in some cases, to have patients withheld from operation by the supposed absence of cancer, because of the presence of hydrochloric acid, when a calm consideration of the clinical symptoms would and should have indicated some serious lesion.

* Read before The Massachusetts Medical Society, June 7, 1904.

In many other cases what can we say? A patient is treated for months or years for a mechanical obstruction, by lavage, medicines, diet, etc., never with more than partial, temporary relief, only to slowly and insidiously develop a malignant growth, to be turned over to the surgeon long after it is too late, robbed of his money, strength, time and courage. Then if operation is done as a last resort and the patient dies, surgery receives all the blame.

The bulk of patients seeking aid of the medical practitioner and of the stomach specialist are medical, and not surgical, from first to last. These are the dyspeptics from alcohol, dietary errors, worry, etc., and they can all be cured far better in any way than by surgery. When we consider the ulcers, acute and subacute, it is probable that a good proportion can be, and are, cured by proper medical care. When, however, we come to relapsing or chronic ulcers I believe that, in the long run, surgery will offer a better outlook with less suffering, time and expense than can be obtained by prolonged internal treatment, limited diet, etc. In the grave cases of hemorrhage, the results of men of larger experience, like Moynihan and others, indicate that in all probability surgery can do more, and with greater saftey, than the time-honored treatment so much used at present. Of perforations, there is no room for argument in the matter of treatment. The possibility of perforation of both gastric and duodenal ulcers should be much more before the general practitioner's mind when treating patients with acute abdominal pain.

I have carefully avoided discussing technic in reporting the cases. The best method applicable to each individual case is far from settled, and it cannot be settled satisfactorily for many years. The internist must be content to let differences in methods be settled by the surgeon, meanwhile resting assured that, although there is much remaining to satisfy him, the simplification and the results are as steadily improving as is possible, and the results as shown in relief of suffering are steadily growing more satisfactory. In malignant cases we have used the Murphy button for the most part, but in other cases, where speed is of less importance, the method with clamps and suture as published by Moynihan has given satisfaction. Gastroduodenostomy by Finney's method we have liked also, but as we grow more proficient in our technic, and what is of more importance, as soon as the general practitioner realizes that stomach surgery is not as serious or fatal as the textbooks describe, I believe that the radical operation will be much more in vogue where now we resort to a simple anastomosis. Indeed, I am convinced of this in spite of the occasional discouraging failures.

No attempt has been made to report the chemical analyses of our cases. In quite a number careful and elaborate examinations were made, while in others only simple tests were used. Until we can collect a large series of several hundreds of analyses made by the same methods and under practically the same guidance, I believe that the discussion of tests made, as in our patients, by many different examiners and under very varying conditions, is only futile. I have tried, first of all, to demonstrate the clinical history just as the general practitioner would obtain it, testing the size, motility and acidity of the stomach, which can be done without elaborate apparatus. By comparing these clinical symptoms and the clinical histories (brief though they may be, but notwithstanding, so often very poignant) with the condition found at operation, I believe we can form some judgment in future as to the actual condition of the viscera before operation.

The cases that have but little interest to us in this report consist of 4 operations for stricture of the esophagus, 3 of which were carcinoma, and 1 a gumma. Two patients were operated on for perforating wound of the stomach, with one recovery. Two cases were explored, one for a supposed foreign body and the other was a man of forty-six who had had a gastro-enterostomy done by Dr. S. J. Mixter, with a McGraw ligature, in August, 1902. Following this operation he was well for six weeks, when his pain and vomiting returned. Often he would go for a week without vomiting, then would throw up food that he had eaten twenty-four hours previously. On the supposition that the gastro-enterostomy opening had closed I reopened the abdomen and found an edematous condition of the omentum. On the stomach on the anterior surface the artificial opening was clear and easily admitted the finger. The stomach had been drawn down into a funnel shape and was apparently draining perfectly into the jejunum. There was no sign of constriction or of impaired drainage. The gall bladder was covered with adhesions and was not palpable. Exploration elsewhere was negative. As there seemed to be no indication for further interference the abdomen was closed.

Two cases were admitted with an undoubted clinical history of gastric ulcer, but both refused operation and they have not been heard from since.

Of the malignant cases, ten were explored and the condition was found too far advanced to allow radical operation or there was not enough indication of pyloric stenosis to warrant a gastro-enterostomy. These cases were closed at once and were discharged from the hospital as quickly as possible.

In detail they are as follows:

No. XI. Male, fifty-two. Referred by Dr. V. Y. Bowditch. Dyspepsia for a year, with occasional attacks of severe griping pains, for which morphia was given. No vomiting, but some relief from eructation. Test breakfast at the hands of a stomach specialist showed no evidence of carcinoma. He was sent abroad for his health, but derived no benefit from the trip, vomiting more or less while he was in Europe, and at that time he noticed retained food in the vomitus. He then regularly produced vomiting

to relieve his stomach of retained food. He recently had lost a good deal of weight and strength. He was much emaciated and cachetic. Slightly to the right of the median line, in the epigastrium, was a hard movable tumor of the size of a hen's egg. He was put at once on rectal feeding for a few days and his condition improved somewhat.

Operation showed a hard growth about two inches in diameter in the greater curvature, extending towards the pylorus, but apparently not originating there. There were nodules in the omentum and colon, both of which were closely adherent to the stomach. Posteriorly the mesocolon was rough and nodular and likewise the major portion of the posterior stomach wall was studded with small metastases. Anteriorly the lymphatics, radiating in all directions, were filled with the growth. No nodules were found in the liver. As the case was hopeless the abdomen was closed. The patient was in good condition at the close of the operation, but in the course of an hour his pulse rapidly failed and he died twelve hours later.

No. XII. Male, seventy. Entered the City Hospital in August, 1896.

Two months before that he began to complain of constipation, soon followed by vomiting once or twice each day, which had continued ever since, and marked loss of weight. He was cachetic, very thin, and below the costal border a small, hard, round mass could be felt.

Operation showed malignant adhesions of the omentum and stomach and a hard, round ulcerating tumor of the pylorus, with dilatation of the stomach and malignant retroperitoneal lymph nodes. As the patient was too sick to warrant any further interference the abdomen was closed, and he died two days later, vomiting continuously. No autopsy.

No. XIII. Male, fifty, entered the City Hospital in April, 1898. Ten and six years before he had had hemorrhages from the stomach. At one time he used alcohol to excess, but had been temperate for the last five years. Seven weeks before entrance he developed pain, which was relieved by taking soft food. There was soreness and a feeling of pressure over the sternum. For a year he had had soreness across the abdomen and had noticed a feeling of resistance in the epigastrium. Three weeks ago he observed a distinct lump. He was losing strength. A hard tumor the size of a base ball could be felt in the epigastrium.

Operation showed adhesions of omentum and intestines to the liver and deep structures. In the posterior wall of the stomach over the pylorus was a malignant growth closely adherent posteriorly. Numerous nodules in the liver, the size of a walnut. As the case was hopeless the abdomen was closed, and the patient died two weeks later of gradual failure.

Autopsy showed carcinoma of the posterior wall of the stomach, the nodules in the liver being due to cirrhosis, not to carcinoma.

No. XIV. Male, twenty-seven years old, entered the City Hospital in July, 1902.

He had had an irritable stomach since the preceding February, marked by diffuse epigastric pain after meals, increasing in severity recently. He had vomited only a few times. Twice he had vomited a small quantity of reddish-brown blood, which the patient thought was fresh. Blackish, constipated stools. For three or four months a tumor mass had been developing in the epigastrium. For several weeks recently, throbbing of the tumor had given the patient annoyance, as he lay on his right side or on his back. He had lost weight and strength and had grown very anemic. Four weeks ago, after a period of severe constipation, he had severe abdominal pain, which at the time was diagnosticated as rupture of the stomach with a local peritonitis. At entrance he had only 30% hemoglobin. In the epigastrium there was a flat, circular, sharply circumscribed tumor, movable, very slightly tender. Under rectal feeding he improved steadily for about four weeks, although at no time did it seem safe to make even an exploration on account of his intense anemia. The hemoglobin increased up to 45%, and his appetite improved so that he was able to take a fair amount of nourishment by mouth. As soon as it seemed safe to explore he was given ether, and a large nodular tumor adherent to the anterior wall was found too extensive for any attempt at radical cure. The wound was closed and the patient was able to return home to Philadelphia in the course of a week, where he died some weeks later. Examination of specimen removed showed it to be sarcoma.

No. XV. Male, forty-eight, entered the City Hospital in April, 1903.

For five weeks he had had constant pain in the epigastrium with constant nausea. He had lost weight and strength and twice had vomited a moderate amount of dark granular material. There was a tumor mass filling the epigastrium to within two inches of the umbilicus, and disappearing under the costal margin on either side. The surface was irregular and dull to percussion.

Operation showed two groups of malignant nodules in the right hepatic lobe, one in the median line and the other in the right flank; a third in the left lobe. In the posterior wall of the stomach was a large mass the size of a small fist, merging into a sausage-shaped tumor lying along the greater curvature. The pylorus was free and open and the stomach not dilated. The wound was closed and the patient was discharged, temporarily relieved, in eleven days.

His later history has not been obtained, but death must have followed quickly.

No. XVI. Female, twenty-nine years old, referred to me by Dr. M. W. White.

Two years before I saw her she began craving food, with immediate relief on eating. There was no definite dyspepsia at that time. By the end of five or six months she lost her appetite and the abdomen felt full at all times. No vomiting, but eructation. Six months later — that is, a year before I saw her — she began to lose weight and had lost about sixty pounds. One week before I saw her she vomited for several days, but without blood in the vomit. The vomiting usually came on two hours after eating and consisted of undigested food. No history of blood in the stools. She did not complain of pain, but a feeling of pressure; otherwise she felt perfectly well. No history of early ulcer could be obtained. There was a well-marked tumor in the epigastrium, moving with respiration.

At operation, in July, 1903, at the Carney Hospital, the anterior wall of the stomach was found to consist of a broad, flat mass of carcinoma, extending up close to the esophageal opening. There were metastases in the omentum. As there was not enough normal tissue in the anterior wall to make an artificial opening, the wound was closed and the patient was discharged in ten days, unrelieved.

No. XVII. Male, sixty-four, referred by Dr. M. P. Smithwick. He gave a history suggesting a relapsing ulcer for a period of many years. Recently he had had vomiting, with loss of strength, and blood in the stomach washings. Hydrochloric acid was present a month or so before I saw him, but on recent examination this had disappeared. For several months he could keep nothing on his stomach, vomiting imme-

diately after eating, liquids as well as solids. He complained of pain most of the time and had been too weak to work for several months. He was emaciated, with some tenderness in the epigastrium and an indistinct nodule.

At operation at the Carney Hospital, there was an excess of serum in the cavity. Over the parietes and through the omentum there were numerous miliary nodules of carcinoma. In the stomach was a tumor the size of an orange, in the anterior wall and greater curvature just below the esophagus, with infiltration extending up to the diaphragm, and along the greater curvature and anterior wall. Adhesions also extended over to the spleen. The wound was closed and the patient discharged, unrelieved, in eight days.

He lived for about two months and at autopsy carcinoma of the stomach was found.

No. XVIII. Male, sixty-three, referred by Dr. Stack. Entered the Carney Hospital in August, 1903. His mother had died of cancer of the stomach.

For several months he had complained of gas in the abdomen, which produced severe enough colic to keep him awake at night, and he had cut down his diet practically to thin gruel. Pain came on about one half hour after eating. He had had no nausea; no hematemesis. He, himself, noticed a tumor two weeks before I saw him. He was pale, waxy, emaciated, and a mass the size of a cocoanut could be felt in the umbilical region, freely movable, not nodular.

At operation there was free fluid in the cavity and a large mass in the anterior wall of the stomach up to within two or three inches of the esophagus and extending down to the pylorus, involving the omentum, in which the major portion of the growth existed. No metastases were found in the liver, but in the anterior parietal peritoneum adjacent to the main tumor. The wound was closed and ten days later the patient was discharged.

Twelve hours after returning home he had a severe attack of pain without vomiting, but with marked dyspnea, which lasted six hours, followed by death.

No. XIX. Male, sixty years of age. Referred by Dr. Smithwick. Mother had died of dyspepsia. Patient had had occasional attacks of indigestion. Eight years ago he began to have gastric pain, relieved by drinking water. This pain came on several hours after eating, the intervals growing shorter in course of time. This pain would persist until he ate more food, when it would be temporarily relieved. He had had no nausea nor vomiting, but was poorly nourished. There was considerable belching.

At operation, at the Carney Hospital, in September, 1903, a hard tumor was found in the anterior wall just below the esophagus, of the size of a fist, together with additional nodules nearer the diaphragm. The pylorus was free and open; no metastases could be felt in the liver. As the growth was too extensive for excision the wound was closed and the patient was discharged in the course of a week.

A month later he reported at the hospital that he had gained weight, and felt well, still eating every four or five hours for the relief of pain. Death must have followed before long.

No. XCVII. Female, forty-eight years of age, referred by Dr. Dewis and Dr. Pettee. Entered the Carney Hospital in June, 1904.

As long as she could remember she had had indigestion, but within the last year she had lost weight and strength, and the indigestion had grown worse. Distress came on soon after eating, followed by vomiting and relief. For three months she had had almost constant epigastric pain, and for two months she had vomited very steadily after eating. No blood in vomitus at any time. Up to two months ago there had been much gas in the stomach, but recently that had not given trouble. Constipation. Examination of stomach showed considerable sour residue. On attempting to test the capacity great pain was produced and not over a half pint of fluid could be introduced.

Operation showed an excess of serum in the abdominal cavity, a diffuse carcinoma of the pyloric half of the stomach, with metastases in the liver, omentum, mesentery of the small intestine, etc. As it was not possible to make an anastomosis satisfactorily the wound was closed in layers and the patient sent home in a few days, unrelieved.

In the following twenty-two cases of malignant disease some attempt was made by operation to relieve the symptoms, at least temporarily. In a few, the operation was clearly inadvisable, to judge from the outcome. But on several of these unfortunate victims operation was done, because the patients had come from a long distance, begging for some slight relief even if the operation should prove fatal. In scarcely any of them have I regretted doing this little to make their death an easier one, or to relieve even temporarily the horrible suffering from starvation and the persistent vomiting that these patients undergo.

It is almost impossible that the discomfort from a rapid anastomosis can begin to approach the suffering from starvation and vomiting. On the contrary the relief that so quickly follows, sometimes within twenty-four hours, is one of the most gratifying experiences that the surgeon, as well as the patient, can enjoy. Of course the earlier operations took longer and were much less satisfactory because of the ignorance of technic and the hesitation that comes in working in a new field where medical and lay prejudice is so strongly against surgical interference.

CASE XX. One of my earliest attempts at relief, was that of a woman thirty-three years old, who entered the City Hospital in October, 1900.

For one year she had been losing weight and strength, without other symptoms. Seven weeks before entrance she began to have occasional cramps, coming on after eating. Then she began to vomit one to two hours after meals, the vomitus consisting of stagnant food. She had much belching, and five weeks before entrance she vomited what looked like coffee grounds, since which time she had remained in bed. She was emaciated and sallow. Just above the umbilicus a hard, nodular, elongated tumor could be felt. Various examinations of the stomach contents were made, but they were of little help except that hydrochloric acid was found absent. At operation a freely movable pyloric tumor was found and pylorectomy was done with clamps and suture. An attempt was made to tie a Murphy button into the end of the duodenum, but it was unsatisfactory and the side wall of the duodenum was joined to the posterior wall of the stomach with a button, making a satisfactory anastomosis. A long chain of infiltrated tissue, supposed to be lymphatic nodes, along the greater curvature, was removed with the excised portion of the stomach. There is no mention in my notes of nodes in the lesser curva-

tures, although half of the lesser curvature was removed in the stomach portion.

She did well for a week, when the external wound was found open for about an inch, with the escape of yellowish fluid. Later this fluid became bilious, the patient gradually failed, and seventeen days after operation died.

The technic was undoubtedly at fault here, and to that can be ascribed the patient's death. I think, without question, that to-day the same operation could be repeated with almost absolute safety.

No. XXI. Male, sixty-one, entered the City Hospital in August, 1901.

Seven weeks before entrance, after swallowing by mistake some strong carbolic acid, he began to have stomach trouble, vomiting food about three hours after each meal. He then reduced his diet to barley and milk, retaining this until the evening, when he would vomit all he had eaten during the day. Much loss of weight, no pain, no eructation, and marked constipation. The patient was cachetic; the stomach capacity 960 cm., hydrochloric acid present, lactic acid absent. Nothing could be felt in the abdomen. For six weeks he had had only four stools. He was treated on the medical side for a month before his transfer to the surgical side, where a diagnosis of occlusion of the pylorus was made.

At operation there was edema of the peritoneum and considerable serum in the cavity, with thickening about the pylorus, which was nearly closed. A longitudinal incision over the pylorus showed a gummatous-like tissue of the walls surrounding the opening, just admitting a director and found with difficulty from within the stomach. The tissues were too thick and the opening too small to warrant a pyloroplasty, so an anterior button anastomosis was made. He was in such a condition of starvation that he was fed through the intestinal incision, at the time of operation, with beef-tea, coffee and brandy. Vomiting persisted after operation, for two days. He rapidly grew worse, the bowels became loose, he grew delirious, and one week after operation died. Shortly before death he was able to take food by mouth without vomiting, but he was so profoundly starved that he was unable to react.

I think there is no question but what this patient would have been saved had he been operated upon in the early stages of his starvation instead of being held for a month, for the purpose of making an accurate diagnosis and to see if medical treatment could not prove of benefit.

No. LXXXVI. Male, forty-seven years old, with sarcoma of the stomach.

Reported in full by Dr. H. D. Arnold in the Boston City Hospital Reports, Series XI.

This patient entered the hospital in March, 1898, on account of pain in the epigastrium and increasing weakness. Eight weeks before entrance he had given up work on account of the pain, which was steadily increasing. He had lost weight. There was some eructation, gas and nausea, but no vomiting. The bowels were constipated. A large tumor was felt in the left epigastric and hypochondriac regions. Examination of the stomach contents was contemplated, but the patient grew rapidly weaker and it had to be given up.

At operation, in the left hypochondrium a large nodular tumor was found, the descending colon being collapsed below the tumor, but above it the transverse colon was much distended. It was thought at the operation, as well as before, that a malignant tumor involved the spleen primarily or secondarily and that the involvement of the bowel was secondary to this. A jejunostomy was made owing to the serious condition of the patient. He improved for a few days, but died a week after operation.

At autopsy the upper colon was found enormously distended. In the stomach, the lesser curvature was found normal except for hemorrhages beneath the mucous membrane, but the remainder of the stomach showed nodular, firm masses beneath the mucous membrane, ½ to 2 cm. in diameter. On the greater curvature near the pylorus was a large excavation with a necrotic mass extending through to the splenic flexure of the colon. The pancreas was evidently involved as its structures could not be made out. "The growth is evidently of mesenchymal origin and should be classed as a mixed cell sarcoma, perhaps better as an endothelioma." (Pathological Report.)

No. XXII. Female, forty-six, entered the City Hospital in August, 1901. Much emaciated, cachetic, starved and slightly delirious. Two weeks before entrance she had fallen into a trench, striking the region of the stomach, and vomiting soon afterwards. For two years she had vomited directly after meals, no matter what food she ate, and she complained of distressed, gnawing sensations, relieved by taking food. The vomitus never was dark colored nor contained blood. On several occasions recently she had vomited large amounts. There was a large mass in the epigastric region extending down to the umbilicus and to the right, somewhat tender and difficult to palpate on account of rigidity.

At operation the pylorus and pyloric third of the stomach were found infiltrated with a hard malignant mass ulcerated at the pylorus. Hard masses were felt in the retroperitoneal space and in the gastrocolic omentum. An anterior anastomosis, with a Murphy button, was made, the patient being in good condition at the close of operation.

The following day she was very weak, the pulse steadily rising, and two days after operation she died.

Partial autopsy showed a tight joint without evidence of a peritonitis.

No. XXIII. Male, fifty-three years old. Entered the medical service of the City Hospital in November, 1901.

A year before, he had distress and epigastric pain about an hour after eating, lasting for several hours, disappearing when the stomach was empty, relieved by hot drinks and hot applications. There was eructation but no vomiting. He had lost weight steadily, but had kept at work up to July, when he grew very weak. Two months before entrance he began to vomit once or twice a week very large amounts, often with dark coffee grounds, and for a week before he was operated on he vomited several times a day. Marked constipation. He was emaciated, pale, and in the epigastrium was a large mass, tender on pressure.

At operation a large nodular mass of the size of two fists was found in the pyloric half of the stomach and deep glands could be felt all through the upper abdomen. The cardiac half of the stomach was not involved, and an anterior button anastomosis was made, the patient standing the operation well.

After the operation he improved and had no vomiting for two weeks. Then the vomiting returned, he gradually lost strength, and died five weeks after operation.

The abdomen was opened through the incision and the button was found in the stomach.

No. XXIV. Male, thirty years old.

Two weeks and a half before entrance to the medical side of the City Hospital, in October, 1902, the patient had had a sudden onset of pain in the epigastric region which had continued up to his entrance. He had vomited persistently without regard to food and was in a condition of acute starvation. He had had similar attacks one, ten and fifteen years ago, respectively, lasting about a week.

He was transferred to the surgical side, and at operation a malignant tumor at the pylorus, firmly adherent to the gall bladder, the ducts and deep tissues, was found. The pylorus could not be freed sufficiently for its removal. The stomach was dilated and the lumen of the pylorus practically closed. An anterior button anastomosis was done and the abdomen closed rapidly. The patient stood the operation fairly well, but failed gradually and died three days afterwards of exhaustion.

No. XXV. Male, thirty-three years old, entered the City Hospital in December, 1901.

Nine months previously he had attacks of colic without nausea or vomiting. Two weeks later there was dull pain in the epigastrium constantly, most marked two or three hours after eating, with nausea, eructations, but no vomiting till the latter part of November, when he vomited a quart of brownish blood. Since then he had only vomited once. He had lost weight and strength, and had been able to do no work for two months on account of weakness. Just below and to the left of the umbilicus was a tender mass the size of a small orange.

At operation a hard malignant tumor in the pyloric third of the stomach was found starting from or close to the pylorus. The omentum was adherent by direct malignant infiltration. There were enlarged glands in the gastrohepatic omentum, behind the peritoneum, while through the omentum itself were a few small nodules. An anterior button anastomosis was made and the wound closed. He vomited a few times after operation, but was relieved by lavage. A month afterward he was discharged. About a year later the patient reported that he was hard at work and in good condition.

No. XXVI. Female, thirty years old, entered the City Hospital January, 1903.

For about three months she had had pain in the epigastrium, vomiting almost everything except milk and lime water. Pain was worse at night, so that she was not able to sleep. The stomach contents showed free hydrochloric acid and the absence of lactic acid. She improved somewhat under rectal alimentation, but when given food by mouth vomited excessive amounts. There was a movable epigastric tumor. No cachexia.

At operation, an excessive quantity of straw-colored serum was found in the abdominal cavity; a large malignant tumor of the plyorus was found infiltrating along the lesser curvature to the esophagus, along the greater curvature to the omentum, and into the great and small intestine in the neighborhood. The stomach wall was thickened and edematous. An anterior button anastomosis was made and the wound closed. She steadily improved after operation and was soon eating solids without nausea or vomiting. Discharged at the end of two weeks to the Convalescent Home.

A month later, however, she returned to the hospital, cachetic, greatly emaciated — but without having vomited -- with edema and ascites; she rapidly failed, and died in the middle of April.

No. XXVII. Male, fifty-four, admitted to the City Hospital, April, 1903.

A history of stomach trouble for six months, with a loss of fifty pounds in weight, beginning with occasional vomiting, increasing in frequency to two or three times daily, always after eating, coming on as a rule within fifteen minutes. No hematemesis, no pain. He was emaciated, and in the left epigastrium there was a distinct prominence. Examination of the stomach showed absence of hydrochloric acid and presence of lactic acid and a dilated stomach. A week after his entrance he was transferred to the surgical side for operation, when the stomach was found with thick, hypertrophied walls, not dilated, rigid and unyielding. The pylorus was thickened but not indurated as from malignant infiltration. It was impervious so far as could be told by examination through the stomach walls. No nodules were felt. An anterior button gastro-enterostomy was made and the wound closed. After operation vomiting ceased, but the patient steadily grew weaker and died without other symptoms, four days later.

No autopsy was obtained and the diagnosis cannot be absolutely established, but in all probability it was diffuse carcinoma of the stomach.

No. XXVIII. Male, forty-nine years old. Referred to me by Dr. J. A. Gordon.

For five years he had been under treatment by a prominent physician for dyspepsia, fermentation and vomiting. He had improved somewhat up to about nine months before I saw him. Then there was recurrence of his trouble with enormous dilatation and fermentation. There was no history of hemorrhage, but the vomitus contained food eaten one or more days previously. There was marked loss of weight, and examination showed a distended stomach, with the lower border half way between the umbilicus and the pubes.

At operation, at the Boothby Hospital, the pyloric third of the stomach was found to be a mass of malignant infiltration extending into the omentum. An anterior button anastomosis was made, and the wound closed. He was soon up, eating heartily of soft solids, and liquids, and returned home in good condition.

Later he went to business regularly, but gradually the symptoms returned, he lost weight, and died several months after operation.

No. XXIX. Female, sixty-two years old. Referred to me by Dr. F. J. Peirce.

Twelve years before, after a fall, she was confined to her bed for five or six weeks and had been an invalid ever since. She complained at the time of injury of much abdominal pain and distention, but had no vomiting. Six months before I saw her, her first attack of vomiting came on and this was followed by nausea, lasting for some months. Then vomiting returned and steadily increased in frequency. No blood nor coffee grounds had been seen. The vomitus consisted of retained food and at times was excessive in quantity. She had lost thirty pounds in the last eight months. No history of stomach trouble in youth could be obtained. Examination showed an emaciated woman with an irregular tumor in the epigastrium. Irrigation of the stomach showed decomposed food.

At operation at the Boothby Hospital, in February, 1903, a hard malignant tumor in the right portion of the stomach along the greater curvature and close to the pylorus, but not involving it, was found. It invaded the mesocolon and the omentum. An anterior button gastro-enterostomy was done. A very much distended gall bladder was found, with two large stones, wedged in the cystic duct, which were removed. The patient slowly gained and was able to take sufficient food to satisfy her hunger, and returned home in good condition, but some weeks afterwards gradually failed and died.

No. XXX. Male, forty-four years old. Entered the Carney Hospital June, 1903, for sarcoma of the testis, which was removed. In the upper right abdomen was a large nodular tumor, which prevented the patient from lying down with comfort and obstructed the pyloric outlet. He had more or less regurgitation, without nausea. Soon after eating, he complained of more or less burning sensation in the stomach. There was another metastatic growth in the right neck. Operation was advised for temporary relief.

At operation a large nodular adherent mass in and about the pyloric third of the stomach, with retroperitoneal and mesenteric nodes, was found. Universally throughout the omentum were small translucent nodules one eighth of an inch in diameter. An anterior button gastro-enterostomy was done and the wound closed. The patient recovered well from the operation and was sent home in a few days perfectly comfortable.

The later history is unknown, but he undoubtedly succumbed to his disease within a short time.

No. XXXI. Male, twenty-seven years old. Was transferred from the medical service of the Carney Hospital, June, 1903.

The patient was in constant pain, with vomiting and marked emaciation. An operation was advised as a palliative measure only.

In the esophageal third of the stomach was found a hard nodular growth extending up to the diaphragm but without evidence of metastases. It apparently blocked the entrance to the stomach so the jejunum was opened, a catheter tied in, and liquid food given at once. He was fed through the tube for several days, at the end of which time the opening into the stomach apparently enlarged, and he was able to take semi-solid foods. He continued taking food by mouth, but rapidly grew weaker and was transferred to the Ward for Incurables, where he died shortly after.

No. XXXII. Female, thirty-five years old. Referred by Dr. Foley of Worcester. Entered the Carney Hospital in September, 1903.

In February of the same year she began to have gastric symptoms, relieved by vomiting, but the symptoms steadily grew worse, the vomiting became sour, she lost weight, and finally was reduced to a diet of liquid peptonoids, on which she had lived for six weeks before I saw her. She was much emaciated, could not sleep at night and had pain in her left side. She had never vomited fresh blood, but examination showed some undigested blood. The pain usually came on from a few minutes to an hour after eating and was relieved at once by vomiting if the vomitus was in considerable amount. She had vomited retained food. A short time before I saw her she had been in a hospital and had derived considerable relief, going for a week or more without vomiting. After this treatment she had been on light mouth feeding for a while, but, as noted above, for the last six weeks had confined her diet to liquid peptonoids. Recently there was temporary edema of the lower extremities. The patient was emaciated, the abdomen showed visible peristalsis, and in the epigastrium above the umbilicus was a tender movable tumor, about an inch in diameter. The stomach was moderately dilated.

At operation a typical malignant growth involving the lesser curvature to the pylorus was found, with recent malignant adhesions of the neighboring anterior tissues. An anterior gastro-enterostomy, with a Murphy button, was made and the wound closed. The patient gained steadily after operation and was discharged in three weeks eating ordinary food.

Five months after operation a letter from Dr. Foley reported that the patient had gained forty pounds, had been able to go about, and was in very comfortable condition, but that recently she had begun to show signs of invasion of the opening with return of vomiting.

No. XXXIII. Male, forty-four, referred by Dr. Webber of Calais, Me. Entered the Carney Hospital in September, 1903.

Since June he had had stomach trouble, beginning with loss of appetite, pyrosis and belching. In July he vomited for the first time, afterwards vomiting from one to three times daily. At times the vomitus was dark colored, but never with fresh blood. Food had distressed him for several months, especially when lying down; pain was absent when the stomach was empty. The lower border of the stomach was at the level of the umbilicus. No tumor could be felt on palpation.

At operation, in the lesser curvature and close to the pylorus, probably involving it secondarily, was a hard nodule the size of an English walnut. In the omentum and mesentery were numerous hard lymph nodes, one of which was removed for diagnosis. A posterior gastro-enterostomy, with clamps and suture, was made and the wound closed.

The patient was soon eating the regular food and returned home at the end of two weeks.

In May of this year the patient reported that he had had no vomiting since the operation, had eaten three square meals daily, and had not lost a day's work; but he was beginning to lose strength and was undoubtedly gradually failing from general malignant infection.

No. XXXIV. Male, thirty-eight years old, entered the Carney Hospital in November, 1903, and was transferred from the medical side for operation. He had complained of stomach trouble for eight weeks, vomiting occasionally one half hour after meals, but for the last four weeks he had vomited everything. There was much gas, epigastric pain and constipation. Examination of the fasting stomach showed eight and one-half ounces residue, free hydrochloric acid absent, lactic acid present.

At operation, by Dr. Bottomley, a hard mass half the size of the fist was found involving the pylorus. The retroperitoneal glands were enlarged; the stomach not much distended. A posterior anastomosis, with clamps and suture was made, some difficulty being found in obtaining sufficient healthy tissue to work with.

The patient was in poor condition and gradually died about two weeks after operation.

No. XXXV. Female, forty-nine years old, referred by Dr. Glennon of Stoughton, entered the Carney Hospital in January, 1904.

For a year she had had indigestion and pain, referred to the stomach, with distress following food. During the summer she was worse and had occasional vomiting. She was very much troubled with gas and constipation. Lavage showed undigested food, hydrochloric acid present and lactic acid absent.

At operation, by Dr. Bottomley, a hard, malignant tumor of the pylorus, with involvement of the glands posteriorly, was found. A posterior gastro-enterostomy, with clamps and suture, was made and the wound closed.

The patient vomited only two or three days after operation, some coffee-ground substance being in the vomitus. She then began to fail gradually, without nausea or vomiting. Then suppression of the urine appeared several days afterwards, followed by death.

No. XXXVI. Male, forty years old, referred by Dr. Hunting of Quincy, entered the Carney Hospital in March, 1904.

A year ago he began to lose weight and complained of dyspepsia at the same time. At first there were eructations of mucus, but during the summer he vomited sour food, usually four or five hours after eating. No blood had been seen at any time. The vomiting came on about every day and constipation was marked. For the last two months he had practically vomited all that he had eaten, but no history of excessive quantity could be obtained. He was constantly hungry, and eating satisfied the hunger in spite of the vomiting. He had lost weight and was markedly emaciated. He had been in one of our large hospitals under medical treatment, recently, growing rapidly weaker. In the epigastrium and left hypochondrium was a nodular superficial tumor, moving with respiration. He was able to digest a little malted milk since he had been on rectal feeding. An operation was advised in the hope that it would at least enable him to take food by mouth until he died of general malignancy.

At operation, a hard nodular mass involving the pylorus and pyloric third of the stomach in both walls was found, infiltrating the liver. It was difficult to obtain enough healthy tissue to make an anastomosis, but an anterior button anastomosis was made and the wound closed. The patient recovered well from the operation, was able to take food comfortably, and was encouraged with the result; but he gradually grew weaker and died nine days after the operation, without having vomited.

No. XXXVII. Male, sixty-five, referred by Dr. Deacon of Milltown, N. B. Father died of stomach trouble at sixty-seven years of age.

For a year the patient had complained of slight soreness in the right epigastrium, but without dyspeptic symptoms. Three months ago there was much gas and he was obliged to sit up in bed at night to relieve the distention. There was slight indigestion at this time, with distress after eating, but no vomiting. His appetite was good. Six weeks ago there was griping pain in the epigastrium and he was unable to sleep. He still had no vomiting, but began to limit his diet to liquids and soft solids. Four weeks ago he vomited after eating, and there was much pain and annoyance from persistent belching, which came on in spells. For two weeks he had been nauseated all the time, vomiting constantly. No blood had been seen until two days before entrance and then only in a few streaks. He had lost thirty pounds in six weeks and had been confined to bed for the last week. He entered the Carney Hospital in April, 1904, emaciated, with a hard nodular mass the size of a fist, in the epigastrium, not very tender. The patient was too sick to justify operation, but he had come such a long distance with a forlorn hope of even temporary relief that I could not refuse at least exploring the abdomen.

At operation the pyloric third of the stomach was filled with nodular masses aggregating a tumor the size of two fists. The growth invaded the adjacent liver and in the latter were metastatic masses the size of walnuts. Along the greater curvatures were large malignant nodes and in the retroperitoneal space were similar smaller nodes. The left portion of the stomach was pale and brittle. There was free fluid in the general cavity, and only by strong tension on the stomach could an area free of growth be brought into the field. To this an anterior button anastomosis was made. Exploration of the inside of the stomach showed nodular growths blocking up the pyloric end. There was no immediate shock from operation. The following day the patient had made a good recovery, but was still weak and there was considerable fresh blood in his vomitus. Two days later there was still some blood, dark in color but much less in quantity. The patient grew weaker, however, rejected his enemata, and three days after operation he rapidly failed and died.

No. XC. Male, fifty-six years old. Referred by Dr. Benner of South Framingham.

Stomach trouble began about fifteen years ago, with distress after eating, but vomiting did not appear until three months ago. He had never vomited blood, but had lost much weight. Examination of the stomach showed a capacity of over two quarts, with retained food, the lower border being below the umbilicus. For years the patient had been under the care of various physicians for dyspepsia, with only temporary relief. A day or two before I saw him he had lost rapidly and was stupid and partially delirious at examination. Operation was requested at any risk and was done at once at the South Framingham Hospital. The stomach was found dilated and distended with gas. In the pyloric region was a hard, scirrhous growth, apparently a carcinoma of the pyloric ring itself. In the neighborhood were numerous small, white metastases extending into the lesser omentum, the greater omentum, the mesocolon and the mesentery, with scattered nodules in the jejunum. The liver was normal. A posterior gastro-enterostomy, with clamps and sutures, was done as rapidly as possible, and the abdomen closed in layers. In both the stomach and jejunum was found very foul, decomposed blood, some of which the patient vomited, although the stomach had been carefully washed out previously. There was severe shock, and the patient died in twelve hours.

No. XCI. Male, sixty-two years old. Referred by Dr. George H. McIntire of Cambridge.

For several years he had had stomach trouble, beginning with dyspepsia, coming on after meals. He had been a commercial traveler for a number of years, with irregular meals, and recalled a number of times when he had attacks of temporary distress, without vomiting. Then the dyspepsia became more persistent, and for the past year it had steadily increased, with vomiting at times. For two years he had not been able to sleep through the night without rising once or twice and taking a dose of soda bicarbonate to relieve the gaseous distention of the stomach. Vomiting began about a year ago, and consisted of poorly digested food, and at times of food that had been retained for over twenty-four hours. He had never noticed blood nor coffee grounds, but had vomited excessive amounts, and in the last few months had lost weight. The distress after meals would come on in about one hour and he was made worse by lying down. He had limited his diet more and more, and when seen was eating very simple food. He had been treated by various physicians — stomach specialists among them; forced feeding had been tried, but attacks of severe vomiting was the main result.

At operation, at the Carney Hospital, a nodular, irregular tumor was found at the pylorus, with extension along the posterior wall of the duodenum for about three inches, making it impracticable to clamp the bowel through healthy tissue in order to perform a pylorectomy. No enlarged glands were found in either of the omenta. A posterior gastro-enterostomy, with clamps and sutures, was done, with a short jejunal loop. In the stomach was some digested blood. Wound closed in layers. Patient in good condition at close. Convalescence was satisfactory and several weeks later he was in excellent condition.

(To be continued.)

MALPOSITIONS OF THE UTERUS; THEIR CAUSES AND TREATMENT.*

BY D. J. BROWN, M.D., SPRINGFIELD, MASS.

When we speak of a normal uterus, in the general acceptance of the term we mean that the fundus should be on a level with the plane of the superior strait, and the os externum should touch a line drawn from the lower surface of the symphysis pubis to the lower margin of the fourth sacral vertebra. This would bring the axis of the uterus very nearly at right angles to the vagina. However, some works on anatomy represent the uterus as having a straight canal, viz.: its axis corresponding to the long axis of the body. Dependent upon respiration, intra-abdominal pressure, body movements, and the bladder or rectum, distended or empty, the uterus changes its position very frequently. This is called the normal range of movements and is controlled by the uterine ligaments, the functions of which are as follows: The round ligaments resist backward displacement of the body; the utero-sacral and vesico-uterine resist the downward pressure or prolapse. The broad ligaments, besides preventing excessive lateral motion, enter largely into the support of the uterus — they are the weight carriers and have a fixed capacity. When the pelvic fascia is anywhere injured, every other portion of the pelvic contents feels the effect of the relaxation. If the uterus is sub-involuted and heavy with blood, the broad ligaments feel the increased weight and they are no longer able to resist the force of gravity; therefore, the uterus remains in its normal position by the concerted action of its several ligaments and the pelvic fascia, which are mutually interdependent for their integrity of action. That the perineum is responsible for the support of the uterus and vagina, I believe has but very few adherents at the present time.

In citing the causes of retro-deviation I shall make use of Krusen's classification.

Class A. Virginal Retro-deviation.

(1) Congenital retroflexion was first recognized by Saxtorph in 1775, next by T. L. Lee in 1849, is usually due to the incomplete development of the anterior and posterior uterine walls.

(2) Schultze attributes puerile retroflexion to congenital shortness of the anterior wall, whence it follows that distention of the bladder, which normally would slightly displace the uterus, completely retroverts it.

(3) Senile atrophy of the genitals, which is associated with shortness of the vagina while the bladder capacity remains unchanged.

(4) Every time the bladder becomes filled, the uterus, as already stated, is placed physiologically in a temporary position of retroversion; hence prolonged over-distention predisposes to this form of displacement.

(5) Habitual constipation resulting in severe straining efforts and increased abdominal pressure during difficult evacuation of the rectum, is a frequent factor, both in virgins and parous women.

(6) Masturbation by relaxing the uterus and the loss of nutritive fluids, is, according to Fritsch, responsible for many cases of virginal retrodisplacement. Hildebrandt found seven such cases in twelve girls addicted to the vice.

(7) Constitutional diseases, such as chlorosis and anemia, tend to relax the uterine supports, cause a disappearance of the adipose tissue, produce constipation and even make the uterine muscle itself relaxed and flexible.

Class B. Parous Women.

(1) Puerperal metritis, or sub-involution: This may be confined to the placental site or affect all parts of the uterine walls. If the placental site be on the anterior wall and the area be inflamed and thickened, this will produce a marked tendency to retroflexion. Chronic or puerperal metritis, by increasing the size and weight of the organ, with corresponding relaxation of the broad and round ligaments, will favor malposition.

(2) Laceration or over-stretching of the pelvic fascia, permitting the development of a rectocele and cystocele, is followed by downward or backward displacement.

(3) Salpingitis, by producing adhesions between the adnexa and the pelvic walls.

(4) Pregnancy may also be a factor, or may be complicated by it.

(5) Pressure from corsets, heavy skirts suspended from the waist, tight clothing, and prolonged pressure from a tight obstetric binder.

(6) Traumatism, blows, falls, or violent muscular effort.

(7) Neoplasms, either intra- or extra-uterine, may by their pressure displace the uterus.

(8) Among the more infrequent and problematical causes may be mentioned impotent husbands, as suggested by Hildebrandt, although Winckel states it is probably a simple coincidence.

(9) A wandering spleen was the direct cause in one instance reported.

Chronic cystitis, which shortens the vesico-vaginal septum by contraction, may produce a retrodisplacement. This form is incurable. (E. C. Dudley.)

Anteflexion is an accompaniment of non-development of the uterus which manifests itself by severe obstructive dysmenorrhea in girls at the beginning of menstruation and is a cause later in life of sterility. Among other causes may be mentioned, over-indulgence in dancing, gymnasium work, wheel riding. Sewing machine running, or severe work of any kind about the age of puberty may act as a derivative to the important menstrual organs, and one or more of them may be left undeveloped. Schultze has described a condition of immobile retroflexion resulting from posterior parametritis. W. L. Burrage has given the subject considerable thought and study and has published two interesting papers. He concludes that the chief cause of the condition is a shortening of the utero-sacral ligaments, which

* Read before The Massachusetts Medical Society, June 7, 1904.

shortening renders it impossible to permanently remove the flexure. Immobile retroposition with anteflexion is seen following labor and abortion from posterior adhesions, from tubo-ovaritis and hematocele. Generally one or both ovaries are found prolapsed or enlarged. Endometritis is almost invariably present. The condition is attended by dysmenorrhea, scanty menstruation or profuse flowing, pelvic pains, frequent abortions or sterility in the married, chronic irritation, bladder irritability, and leucorrhea. Where there is laxity of the uterine supports, the round, broad and utero-sacral ligaments associated with softness, fatty degeneration and want of tone of the uterine tissue, we have a pathological condition first mentioned by Pozzi in 1896 and afterwards described by Edebohls, known as excessive mobility of the uterus. The laxity of the ligamentous support is the essential condition. Add to this softness of the uterine tissue, and you explain the cause of flexions. If such a patient be examined by a number of men, the uterus will be found in different positions at each examination. I well remember such an occurrence. Each examiner made out a different position, consequently each thought the other had erred. According to Edebohls a diagnosis of excessive mobility of the uterus is made in the following manner: "Say we find the uterus, on bimanual examination, in anteversion or anteflexion, — push the cervix toward the symphysis by the intra-vaginal finger carried into the posterior fornix of the vagina, at the same time crowding the body of the uterus backward into retroversion by the fingers of the other hand upon the abdomen. An excessively movable uterus is thus readily retroverted and, moreover, remains in retroversion after withdrawal of the fingers from the vagina and abdomen, or returns but very slowly and sluggishly into a position approximating the normal." In this it differs from the uterus with normal mobility, which either would be replaced into retroversion of the second degree, or if forced into the latter position, immediately springs back into normal anteversion when released from the pressure of the fingers.

Symptoms. — Besides the usual symptoms, we have disturbance of the lower part of the intestinal tract, namely, tympanites and readily provoked irritation of the colon and rectum, as manifested by alternate constipation and looseness of the bowels, occasionally membranous enteritis, neuralgiæ and dysæphesiæ of a fugitive or wandering character, generally not severe, affecting the lower end of the trunk. This condition may be present in Glenard's disease. The symptoms of this condition are explained by irritation of the hypogastric plexus of the sympathetic.

A study of the treatment of malpositions of the uterus is unsatisfactory. A few years ago when corrections of uterine displacements became the surgical craze, one operative method after another was brought forth until at the present time the number is legion. Some of them are as unsurgical as others are surgical. How shall we best treat these conditions? The treatment of uterine displacements must have two distinct purposes in view: first, the bringing forward of the uterus to its normal condition; second, its retention therein. The vexed question is how to retain it there. Taking into consideration the wide range of mobility exercised by the normal uterus, a careful non-surgical and medical treatment should be first thoughtfully considered, being guided by the general condition of the patient, the symptoms complained of, duration of the displacement, and the complications, if any. What changes have the surrounding structures undergone?

The non-surgical treatment of uncomplicated retroversion is as follows: Carefully replace the uterus by bimanual manipulation from vagina and abdomen. If the vaginal manipulation fails, transfer the fingers to the rectum. If you are still unable to reduce it, try the knee-chest position. If all these measures fail, an anesthetic should be administered. This completely relaxes the patient and there will be no trouble in the reduction of the organ. If the displacement has been of short duration a well fitting pessary may be used immediately after reposition; on the other hand, if the displacement has been of long duration, the daily use of sterile tampons saturated with either ichthyol or glycerine and packed firmly against the cervix would be advisable, until all tenderness had disappeared. A Hodge-Smith pessary of proper shape and well fitted may then be used. This pessary will temporarily support the uterus in its normal position, besides relieving the abnormal strain. It gives the over-stretched sacro-uterine and round ligaments, which contain muscular fibers, as well as the vaginal walls, a chance to regain their normal tone. Also the lower bowel, which becomes atonic from constant pressure. As we learn to differentiate our cases more carefully, the prejudice which exists against the use of the pessary will promptly subside.

Besides this treatment, the patient should be given general tonics, especially those which have a tendency to tone muscles. Hot vaginal douches containing alum, at a temperature of 115°, twice daily, patient lying in the recumbent position. The patient should also be advised to assume the knee-chest position three or four times daily, two minutes each time, and with finger retract the fourchette, thus allowing air to enter the vagina, which distends the vaginal vault and counteracts intra-abdominal pressure. Patient should also be urged to lie upon the abdomen while sleeping. This treatment should be carried out during a period of at least two or three months. In a certain percentage of cases your efforts will be rewarded by good results. This may not meet the opinion of some whose teaching is always operative, but results often give us decided opinions of our own.

When, however, the retractile power of the utero-sacral ligaments is completely lost, the following simple operation, devised by A. H.

Goelet, is to the writer a step in the right direction. In 1899 Dudley, in a paper before the Chicago Gynecological Society, said, "We are now prepared to announce the great general principle of mechanical support as follows: If the cervix be normally placed within an inch of the hollow of the sacrum, the body of the uterus will, in the absence of complications, usually take care of itself." The operation about to be described aims at overcoming the displacement by holding the cervix permanently backward in the hollow of the sacrum and doing away with the necessity for a pessary, making use of the posterior vaginal wall for the attachment of the cervix, which, under normal conditions, is firmly connected with the anterior wall of the rectum.

Technic. — Patient is placed on the back in the exaggerated lithotomy position, vagina and vulva are cleansed in the usual manner by scrubbing, then the surface of the vagina and cervix are dried and painted with tincture of iodine to stain it and render it aseptic, or a solution of methylene blue might be used for this purpose. An area about one-half inch square upon the posterior surface of the cervix is denuded of its mucous membrane and a similar surface upon the posterior vaginal wall, well up in the sulcus, behind the cervix, is likewise denuded. These denuded surfaces are then approximated by deep sutures, three or four of which will suffice. Material, catgut or silkworm gut. A tampon of gauze is placed against the cervix to take the strain off the sutures and keep the surface of the vagina dry. Dressings are removed on the second day and may be renewed or not, as the judgment of the surgeon may dictate. Patient is kept in bed one week and encouraged to rest on either side rather than upon the back. If silkworm gut is used, it may be removed in two or three weeks.

The Alexander is a popular operation in uncomplicated cases of retro-deviation. Its advocates claim that the round ligaments will hold the uterus long enough in position to allow the utero-sacral ligaments to regain their normal tone. Many objections are urged against it, with all of which you are familiar. In two instances where the writer has performed the Alexander, a diseased appendix was also removed through the right incision, which was small, and carried through to the abdominal cavity. Both made excellent recoveries and no hernia followed.

In anteflexion due to muscular non-development, Martin advocates the use of electricity and has had exceedingly good results. He also recommends large and stimulating hot douches night and morning, supplementing these douches by an antiseptic douche immediately before treatment. The length of time required to carry any case to a successful termination is from three to six months. This might be urged as a serious objection. He also advocates proper exercise, general tonics, and laxatives if necessary.

In choosing operative procedures in cases of anteflexion, we have Dudley's operation, which consists in a division of the posterior wall, past the utero-vaginal attachment nearly to the utero-peritoneal fold in the pouch of Douglas; or, a modification of the same now in vogue at the Free Hospital for Women, a description of which appeared in its bulletin, Vol. I, No. 3, January, 1904. The success obtained has been remarkable and is worthy your consideration. Simply to dilate and curette, in this form of displacement, as is generally done, and expect good results, is a practically useless procedure. In extreme cases the anterior lip may also need attention.

In immobile retroposition with anteflexion, Burrage advocates, besides curetting, a division of the utero-sacral ligaments through an abdominal wound, and suspension of the uterus.

Where we have retro-deviation plus adhesions, it may be corrected in the following manner: Make a transverse incision through the posterior fornix, break up the adhesions, carry the uterus forward, then pack gauze into Douglas's pouch and also beneath the cervix, pressing it well upward and backward. The adhesions thus formed will lead to a correction of the displacement.

The treatment of excessive mobility of the uterus is essentially the same as that for movable retroversion of the uterus. A pessary will effect a cure in a percentage of these cases. Edebohls advocates Alexander. The writer would suggest cervico-vaginal fixation to those who object to wearing a pessary.

In retrodisplacement it sometimes happens that one or both ovaries may be prolapsed. This condition very frequently is the cause of more disturbance than the malposition of the uterus itself. When the prolapse in question is due to a lax and elongated ovarian ligament, to simply correct the malposition will not relieve the patient. The ovaries must also receive your attention. Two methods of treatment are advocated: first, by taking up the slack or making a fold in the ligament and stitching it with either silk or cat gut; second, as advocated by Dudley, stitching the ovary to the posterior surface of the broad ligament. In the absence of severe complications, this may be done through the vaginal route, when it is also possible to shorten the round ligaments, or simply correct the ovarian prolapse and do the posterior cervico-vaginal fixation. Of course, where the complications are extensive, viz., deep infection involving intestines, appendix, etc., the suprapubic route would offer better facilities.

The writer's work through the vaginal route, which includes a number of cases of resection of the ovaries, tubes, shortening of round ligaments and hysterectomies, has been very gratifying. It was really a stepping stone to thorough study of plastic work.

Presumably it may be said that the nearest approach to an ideal operation in uncomplicated retrodisplacements, is the one which takes up the slacks of the utero-sacral and round ligaments.

We now come to the consideration of complete prolapse. We have the following factors to consider: Backward displacement, including relaxation of the utero-sacral muscles; a sub-

involuted uterus, probably a ductile cervix, and a relaxed vaginal outlet, or a complete tear. We therefore have certain fundamental facts that must be considered: first, the whole vaginal walls are inverted. There can be no uterine procedenture without a corresponding vaginal inversion, unless it occur as a part of Glenard's disease, and then the vagina may be inverted by the sagging downward of a long ductile cervix; third, the anatomical relations of fascial structures; fourth, the intact levatores ani is the most important factor in preventing this form of displacement. The indications in this form of displacement are clearly as follows: First, to cause involution of the uterus, thus rendering it lighter and capable of support by the pelvic fascia in the broad ligaments and elsewhere. To renew the tension of the pelvic fascia throughout the pelvis, that proper support may be given to the levatores and the connective tissue and its vessels and the rectum and bladder. When this is thoroughly done, we will be able to discard various auxiliary operative procedures, such as the Alexander ventro-fixation and others, and stand squarely by the results of our plastic work on the pelvic floor.

Previous to any surgical procedures, Emmet advocates preparatory treatment. After replacing the uterus and pushing it up as far as may be in the pelvis, the patient is placed in bed, the foot of which is raised from 12 to 18 inches from the floor. The object of this treatment is to cause contraction of all the pelvic veins with a resulting involution of the uterus and vagina. This treatment must, however, be carried out for some time, which will be urged as a serious objection, as many poor patients cannot afford the loss of time. Munde's custom was to amputate the cervix high up and leave a granulating wound at the fornix, which, by its contraction, was to hold the cervical stump backward, when the fundus must fall forward.

If the cervix is repaired, two objects must be attained: first, the complete removal not only of all scarred tissue, but, equally important, of all diseased tissue; second, the excision must be carried down to the plane level with the bottom of the tear where it touches the canal. You may choose between Emmet's and Reynolds' anterior colporrhaphy. In doing the posterior operation the writer would advise carrying the denudation the whole length of the vaginal wall. I have succeeded in obtaining splendid results in five cases operated upon according to the above described methods.

To maintain a prolapsed uterus in a normal position by means of a series of plastic operations is by no means an easy task; still, there is less danger to the patient than in doing either a ventro-fixation or a suspension. The writer has abandoned the operation for ventro-fixation for the following reasons: It is unscientific, as it places the uterus in an arbitrary position — the uterus is made to support rather than be supported. It is a barrier to normal gestation. The circulation is more or less disturbed as the vessels are put on the stretch, and vesicle irritation is sometimes caused by dragging the uterus beyond a certain level, which is certainly done in this operation. Again, no operator can predict in advance how large or how small the resulting adhesions may become. Just here is the element of uncertainty and danger. If small they will probably stretch into a suspensory ligament; if dense and large you may expect trouble.

The writer is opposed to creating artificial supports. Nature has furnished enough if proper use is made of them. After the menopause there may be no such objections as to making a fixed uterus support relaxed tissues, for then it is a functionless organ.

Soon after Dr. Gilliam published his operation known as "round ligament ventro-suspension for retrodeviations," the writer performed it in a number of cases. From a physiological standpoint, it would seem that a suspended rather than a fixed uterus would better meet the demands of gestation. Unfortunately, the writer has not had an opportunity to study the effect of gestation upon ligaments so treated. Like fixation, there are serious objections to it, — the great possibility of intestinal strangulation and obstruction. Again, the uterus is in an arbitrary position, one set of supports doing the work of all. How long ligaments treated thus will act as a sustaining power, is a question the writer is not prepared to answer.

In failures, after a series of plastic operations, the intrapelvic method advocated by Dr. Henry T. Byford, for prolapse and procedentia, is worthy of consideration as it makes use of every available support.

When a hysterectomy is decided upon the vaginal route is preferable, uniting the anterior and posterior peritoneal margins, and then an end to end approximation of the stumps of the broad ligaments ought to form such a perfect support that there will be no danger of any future hernia.

In conclusion, permit me to say that whichever method you may choose, it will depend upon the degree of skill with which the work is executed, whether the outcome will be success or failure.

DISCUSSION.

MALPOSITIONS OF THE UTERUS.

DR. J. C. IRISH, of Lowell: I beg to differ somewhat radically from the reader in regard to the treatment of retrodisplacement and prolapse of the uterus by ventral suspension. I am very much at a loss to understand why it has become so much the fashion to criticise or condemn this operation, or why, when we have at our hands so simple and so effective a means of correcting retroversion and prolapse, so many other more difficult and uncertain procedures should be resorted to.

The four principal criticisms of the after results of the operation are: First, that there is danger of obstruction of the bowels by being caught in the resulting ligament; second, dystocia of labor; third, that the uterus is still left in an abnormal position; fourth, that it is an unsurgical procedure.

I have had a long experience with this operation, going over a good many years, and including more than

one hundred and fifty cases. In no instance in my own practice has obstruction of the bowels occurred from ventral suspension, nor indeed have I ever heard of a case. This danger, I am certain, is very much more imaginary than real. In regard to the dystocia of pregnancy, a few years ago Dr. Noble of Philadelphia investigated over eight hundred cases of ventral suspension in reference to this point. The only dystocia of pregnancy or labor that he established was the following:

In some cases as the pregnant uterus enlarged, there was a thickening of the anterior muscular structure of the uterine body and neck which encroached upon the entrance to the pelvis and interfered with the engagement of the head. The os uteri was also carried backward towards the sacrum.

This single dystocia in labor, due to suspension of the uterus (and this is the only one that is shown), I believe to be entirely avoidable. I am very certain that this faulty development of the pregnant uterus has resulted from the introduction of the sutures on the posterior uterine surface. It is very evident that such forced right-angled attachment to the abdominal wall might interfere with uterine development. By placing the ligatures on the upper anterior surface of the uterus this whole difficulty would be prevented. If my conclusions are correct, the operation should be absolved from the charge of producing this dystocia of labor. It may be true that the uterus after suspension is not left in an exactly normal position, but it is near enough normal so that it ceases to give any trouble to its possessor, and the patient with the suspended uterus is exactly as well satisfied with it as though the position were perfect. At any rate, the patients consider themselves perfectly cured.

This is characterized as an unsurgical operation, but it seems to me that an operation which is so entirely simple, so easy to do, free from danger, and which perfectly corrects the disability for which it is done, is really a very surgical one. Finally, from the result of my own experience and that of my confreres who do ventral suspension, I believe that no other surgical procedure should be considered in the treatment of uterine retrodisplacement or prolapse.

DR. J. G. BLAKE, of Boston, said that he had not seen any unsatisfactory results follow the operation of suspension of the uterus. If danger of strangulation of intestine arose from the adhesions between the fundus and the abdominal wall, this danger is just as great before as after the menopause; yet many writers say that the operation is indicated after the child bearing period, but not earlier. There are definite indications for suspension, in retrodisplacements and moderate degrees of prolapse. In all the cases he has seen, either in hospital or private practice, no trouble has arisen following the operation, and in almost every case partial or complete cure has resulted. The actual cases of strangulation reported as a sequel are extremely few.

SUBPERIOSTEAL FRACTURES OF THE HUMERUS IN CHILDREN.

BY J. S. STONE, M.D., BOSTON.

THE following cases presented themselves in the General Surgery Service at the Children's Hospital and seem of sufficient interest to be worthy of report. They illustrate the dangers of overlooking fractures in children, and call particular attention to the symptoms by which subperiosteal fractures of the surgical neck of the humerus may be diagnosed in the absence of the usual signs of fracture. The medico-legal importance of the recognition of such cases as those to be described is obvious.

For the radiographs the writer is indebted to Dr. Percy Brown.

CASE I. M. F., a girl eleven years old, came to the Surgical Out-Patient Department of the Children's Hospital on May 18, 1903.

Two days before she had fallen from a swing injuring the right arm. The skin had been much inflamed by being rubbed at home with kerosene. No bony lesion was found. There was complete inability to raise the arm from the side. The elbow and forearm were moved with perfect freedom. The child was extremely nervous and of poor physique. The disability was thought to be chiefly hysterical.

A sling was applied. Some atrophy of the deltoid developed later. In a fortnight the arm could be moved much more freely and could be raised somewhat. After six weeks motion was free in every direction. The functional result was perfect. Three weeks later the child was examined more thoroughly. There was then to be felt, perfectly plainly, an irregularity in the neck of the humerus. There was slight forward projection of the upper end of the lower fragment and slight forward bowing. The callus was very small.

The radiograph taken at that time, nine weeks after the injury, confirmed this clinical diagnosis of fracture which was, however, made only after the lapse of two months and in view of the second and third cases.

CASE II. M. S., a girl ten and a half years old, was brought to the Accident Room of the Children's Hospital on July 6, 1903. She had that day fallen down four or five steps hurting her left arm. She was unable to raise the arm from the side. She was examined very carefully in the accident room and no bony injury was found. The diagnosis made was injury to the deltoid. A sling was put on and the mother was told to apply an ice bag to the shoulder. Next day she came back to the Surgical Out-Patient Department. There was then marked swelling and slight ecchymosis in front of the neck of the humerus. There was slight thickening connected with the bone at the same place. The girl could move the forearm and hand freely. The arm could be moved fairly freely except that it could not be abducted. Passive motion was free in all directions, and caused but little pain.

A radiograph was taken at once which showed a transverse fracture of the surgical neck. There was absolutely no displacement laterally. The upper end of the lower fragment projected forward a little and there was slight impaction of about a quarter of an inch posteriorly causing a slight forward bowing.

No attempt was made to correct the slight deformity. The child was treated by coaptation splints and a shoulder cap with a wrist sling. Considerable atrophy of the shoulder muscles came on within a few days. The callus which resulted was small. Union was firm in six weeks and the child was discharged with a perfect functional result.

CASE III. M. O'C., a girl aged six and a half years, was brought to the Surgical Out-Patient Department of the Children's Hospital on July 18, 1903.

Two weeks and a half before she had fallen off a fence. Afterward in spite of the fact that she had no pain whatever she could not raise the right arm from the side. She could use the forearm and hand perfectly but was brought in because of the continued disability at the shoulder which was not diminishing at all.

There was considerable atrophy of the deltoid and supraspinatus muscles, and slight of the infraspinatus.

There was complete inability to abduct the arm. Other motions were free and caused no pain. The hand could be raised above the head when the humerus was carried directly forward. A very slight bony projection could be felt in the region of the surgical neck. The radiograph showed a transverse fracture of the surgical neck. There was very slight displacement forward of the upper end of the lower fragment with slight impaction posteriorly and a slight resulting forward bowing. A callus was forming. A shoulder cap and wrist sling were applied. The resulting callus was small.

The child was discharged with a perfect functional result at the end of seven weeks.

CASE IV. H. C., Jr., a boy of twelve years, entered the General Surgery Service of the Children's Hospital on Oct. 24, 1903.

A few hours before he had fallen off a trapeze striking on his left arm and shoulder. Since the accident he had been unable to raise the arm from the side and any attempt to do so caused pain. The motions of the forearm and hand were free but there was absolute inability to raise the arm from the side, and passive motions at the shoulder caused slight pain. The head of the humerus rotated in normal position. There was no crepitus. The only deformity was a slight fulness over the anterior surface of the humerus just below the head. There was slight tenderness at this point. There was slight shortening. Within a few days slight ecchymosis appeared along the upper part of the biceps. The radiograph taken the day of the injury showed a transverse fracture of the surgical neck with slight impaction and slight forward and inward bowing. The boy was treated with a wrist sling and swathe and axillary pad. After six days in the hospital he was sent to the Surgical Out-Patient Department. In six weeks he was discharged with a perfect functional result but there remained even at the end of six months a very slight projection forward on the anterior surface of the neck of the humerus.

CASE V. M. T., a girl of eleven years, was brought to the Surgical Out-Patient Department of the Children's Hospital on Dec. 30, 1903.

Two days before while playing she had fallen with the left arm outstretched. Another child fell across her. Immediately there followed inability to use the arm. The mother noticed tenderness and some ecchymosis about the shoulder. The pain was considerable.

Examination showed considerable atrophy of the deltoid and slight of the supra- and infra-spinatus muscles. There was slight fulness and tenderness in front of the surgical neck of the humerus. Passive motions of the arm were normal, but there was absolute inability to raise the arm from the side, especially when the forearm was supinated.

The radiograph showed a fracture of the surgical neck with very little displacement. A shoulder cap and wrist sling were applied. In three weeks a firm, small callus could be felt. In five weeks the child was discharged well with perfect motion.

These five cases illustrate the risk of overlooking subperiosteal fractures in children.

In the first case the fracture was completely overlooked and the trouble was regarded as chiefly hysterical. The shoulder was carefully examined by several competent observers. It was true that the child was extremely nervous and excitable, but the real nature of the injury was not detected until the next two cases threw additional light upon it. Fortunately the arm was kept quiet in a sling so that in spite of the inefficient treatment the ultimate result was perfectly satisfactory.

In the second case the injury was thought to be to the deltoid when the child was seen in the accident room. Next day when seen in the Out-Patient Department the increased swelling and slight ecchymosis showed that there was some more serious injury. The swelling was greatest anteriorly just below the head of the humerus. The radiograph established the diagnosis at once. Fortunately a sling had been worn and so further harm had been prevented, though the fragments may have moved slightly if one judges by the ecchymosis and swelling.

With the first two cases in mind the diagnosis was at once suspected and promptly confirmed by the radiographs in the other cases, in spite of the fact that the objective symptoms, aside from the inability to use the deltoid, were so slight.

The cases are so similar, in fact so nearly identical, that it seems that the diagnosis should be made with assurance from the clinical symptoms without the aid of the radiograph. Each occurred in a child beyond the age at which greenstick fracture is most common. Each resulted from a fall upon the outstretched arm. In each there followed absolute inability to use the deltoid. Each child could with varying hesitation and difficulty raise the hand to the face and the top of the head but always with the arm kept as close to the side as possible. In each, passive motions in all directions could be made to the full normal limits and were guarded by but slight spasm. Each had a slight atrophy of the deltoid and scapular muscles.

The deformity in each case was trifling. Each had a very sharp, bony ridge on the anterior surface of the neck of the humerus just at the seat of fracture; but this deformity might easily be overlooked unless attention was directed to its exact location. Each had slight localized tenderness at the seat of fracture. Each had very slight pain about the shoulder. The two signs of fracture ordinarily sought, crepitus and abnormal mobility, were conspicuously absent in each case.

These injuries belong to what may be called subperiosteal fractures. Greenstick fractures occur most frequently in somewhat younger children. The latter term should be confined to those cases in which the cortical bone on the convex side is broken but on the concave side is merely bent at the point of fracture. In a true greenstick fracture there is thus always an angular but never any lateral displacement. In each of these cases the radiograph showed the fracture to be transverse with slight lateral displacement. In none of these cases except the fourth was the impaction alone sufficient to have maintained the fragments in their relation to each other. This is shown by the radiographs and perhaps by the absence of shortening. Impaction may mask a fracture, but in children the absence of marked deformity, the absence of

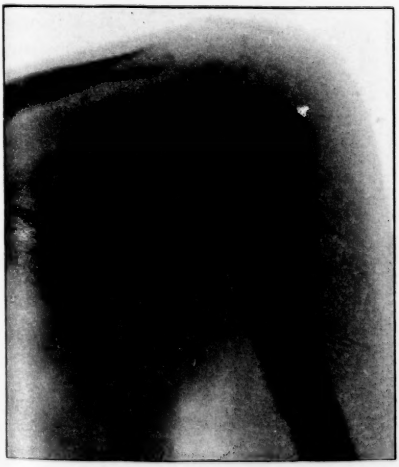
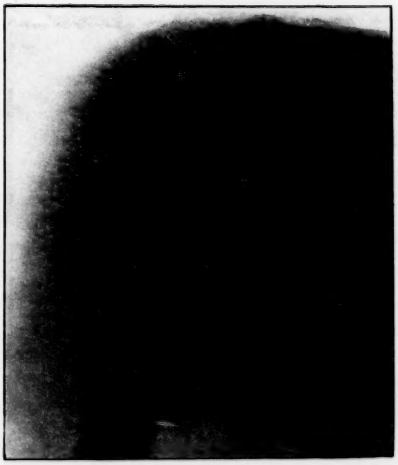
CASE IV. October 24, 1903.



CASE III. July 18, 1903.



CASE V. December 30, 1903.

crepitus, and the absence of abnormal mobility are to be attributed in part to the slight impaction, but chiefly to the toughness and strength of the periosteum.

When after a fall on the arm or shoulder children are unable to abduct the arm but present none of the other signs of fracture or dislocation and are able to move the arm in other directions most careful examination should be made to determine localized tenderness anteriorly just below the head of the humerus, together with a slight irregularity in the contour of the bone at the same point. These signs are sufficient to establish the diagnosis of fracture of the surgical neck, and should deter one from further attempts by rough handling to secure crepitus or mobility.

THE PHYSICAL RELATIONSHIP OF FINSEN LIGHT, RONTGEN RAYS AND RADIO-ACTIVITY.*

BY WALLACE C. SABINE, A.M., CAMBRIDGE,
Assistant Professor of Physics, Harvard University.

There has recently come into medical or surgical use three physical agents or processes, — Finsen light, Röntgen rays and the radiations of radio-active substances. All three are capable of producing sciagraphs, though of varying excellence. All three produce somewhat similar changes in normal and diseased body tissues. They are thus related in their effects, and the present purpose is to trace any physical relationship that may be the basis of this similarity. All reference to the conditions under which they are produced and the method of handling them will be omitted, and only their essential natures considered, — Maxwell's electromagnetic theory of light, of course in its simplest form, J. J. Thomson's highly probable hypothesis in regard to the nature of Röntgen rays, and the commonly accepted but rather complex conception of radio-activity. Finally, in looking for that which all three have in common, we shall find it in their so-called ionizing effect, — the breaking of molecules into subatomic particles, charging the larger with positive and the smaller with negative electricity. This effect common to the three is perhaps the intermediate process preliminary to the final physiological result.

The light medically rechristened as Finsen light has long been known to physicists as ultra-violet light, and known to have many remarkable physical effects. It differs from visible light only in the frequency of its vibrations. Visible light in turn differs only in frequency from the electromagnetic waves predicted by Maxwell, first discovered electrically produced by Hertz, and later made of practical use in a sensational manner by Marconi. To understand the nature of Finsen light, therefore, one has only to understand the nature of the waves of wireless telegraphy. While the difference in frequency and in the length of waves is enormous, in essential nature the two are identical.

* Read before The Massachusetts Medical Society, June 8, 1904.

The conditions of wireless telegraphy are so familiar to every one that it furnishes an excellent starting point for the explanation of the nature of the electromagnetic waves and of the ether. When the electricity surges up and down the vertical wire at the sending station, and this occurs whenever a spark passes, waves radiate from it in all directions horizontally. These waves have a dual nature. They consist of electrical stresses vertically — that is to say, parallel to the wire — and magnetic stresses horizontally. This point is, perhaps, worth elaborating slightly. The ether has three known attributes. These are ordinarily spoken of as its power to transmit electric, magnetic and gravitational forces. The mental picture which the physicist has before him is a little more definite than this. He usually pictures to himself the ether as having some sort of mechanical structure, and a number of crude models have been devised by different men. These, however, are most unsatisfactory, and the only safe statement is that the ether is capable of transmitting an electric and a magnetic stress. But his working conception is that an electric charge actually alters the condition of the ether; that this spreads to greater and greater distances; and that this condition of the ether is of such a nature that any other electric charge, which in the unaltered ether would experience no force, will, in the altered ether, experience a force urging it in a particular direction. Further, the ether is of such a nature that a magnet alters it, first near at hand, but in a very short time at very great distances. This change in the ether when completed differs from the former change, for now a magnet is necessary to detect it. And, moreover, a most important fact is that a *moving* magnet or a moving electric charge produces both changes in the ether at the same time. Considerable is known in regard to these stresses in the ether, — for example, their velocity of propagation, but not enough is known to make it possible to construct a detailed mental picture. The ether also transmits gravitational stress, but nothing is known in regard to this, not even the velocity with which it is transmitted.

Returning to the waves of wireless telegraphy the application will be evident. When the electricity with which the wire is charged surges up and down, it changes the ether in its immediate neighborhood, producing some modification, we know not what; we only know that it spreads like an exceedingly rapid contagion, — one hundred and eighty-six thousand miles a second, and that, on finding at any point an electric charge or a magnet, exerts on it a force. As the electricity surges first up and then down the wire, the modification of the ether is reversed, and waves are formed. Ordinarily in wireless telegraphy these waves, notwithstanding their enormous velocity, are about a mile in length. Were the sending wire short, the waves would be proportionately short. This process of shortening the conductor over which the electric oscillations take place has been carried so far that waves have been obtained only about one eighth of an inch

in length, and, could this process of getting shorter and shorter waves by using smaller and smaller oscillators be carried far enough, they would be identical with visible light, — a little farther, and only a little farther, and the result would be Finsen light. Throughout all this the point to be remembered is that these waves are merely such changes in the ether that they exert a force on a magnet if they meet a magnet, or on an electric charge if they meet an electric charge. With the magnetic effects we are not here concerned, for the tissues of the human body are almost wholly non-magnetic, not quite, but almost wholly so. With the electric forces exerted by these waves we are concerned, for every molecule of the human body carries positive and negative charges. The application of all this, however, will be made later.

Röntgen rays are in many respects similar to light rays. Here, however, the source is not an oscillating electric charge which gives out a train of waves, but a negatively charged particle abruptly stopped by striking against the platinum disc in the center of the exhausted bulb. The result of this sudden stoppage, J. J. Thomson has shown, is a very thin wave, or, as he calls it, a pulse sent off through the ether. These pulses are, like light waves, electromagnetic, but instead of being in a train are single, are numerous as the number of bombarding particles is great, but only one pulse arises from each bombarding particle. The light waves and the pulses differ in another important respect. The Röntgen pulse is exceedingly thin. Thus, the length of a light wave is such that if two points were placed at a distance apart equal to the length of the wave, the most powerful microscope would just be able to resolve them. A Röntgen pulse is only about one ten-thousandth as thick. This exceeding thinness is the source of its great penetrating power. Such is J. J. Thomson's hypothesis in regard to the nature of Röntgen rays. The proof of this hypothesis might be found in a measurement of the velocity of the rays. Should the velocity be equal to that of light, the hypothesis would stand confirmed. Only two measurements have been made, by Brunhes and by Blondlot. The velocity was found to be the same as that of light; but unfortunately the method employed was faulty in the extreme. Moreover, further doubt has been thrown on this work by the subsequent claim by Blondlot of the discovery of N rays — an observation which no physicist of high standing has been able to repeat, although many have tried. There is, therefore, no direct evidence of this kind supporting the hypothesis advanced by J. J. Thomson. Nevertheless, it stands as the most probable explanation of Röntgen rays, and is generally accepted.

The explanation of the radiations from radio-active substances has probably been made familiar by many recent discussions, particularly by Rutherford, who has contributed so much both theoretically and experimentally. These radiations apparently consist of the emission of positively charged particles, negatively charged particles and ether pulse. The phenomenon is just as if an atom of radium in its minute structure consisted of two sizes of particles: the large, about the size of a hydrogen atom, charged with positive electricity, the others very much smaller charged with negative electricity, and, through some power, in regard to which there is absolutely no adequate hypothesis, this atom would throw off with tremendous velocity these particles. The positively charged particles form the so-called alpha rays, the negatively charged particles the beta rays. As a necessary consequence of any such process we should expect, as pulses in the ether, the so-called gamma rays. For just as the sudden stoppage of a rapidly moving electric charge causes an electromagnetic pulse in the ether, so the sudden starting of an electric charge must produce a pulse in the ether. Thus the Röntgen rays and the gamma rays are exactly the same in nature, and differ — if they differ at all — only in thickness. Whether the one or the other is thicker depends on whether it takes a longer time to stop the particles bombarding the platinum vane, or to start the particles off from the disrupting atom. So on this depends their relative penetrating power. The larger positively charged particles constituting the alpha rays, because of their size and comparatively low velocity, have but slight penetrating power, and in consequence are of only remote medical interest. The negatively charged particles and the gamma pulses have much greater penetrating power and are pertinent to the present discussion.

Coming then to the physiological problem we have the effect of three physical processes to consider, — a train of ether waves, ether pulses and a bombardment of negatively charged matter. Of these, the first two have a good deal in common. It is almost axiomatic to say that Finsen light and Röntgen rays, being purely phenomena of the ether, exert their first effect on atomic matter, and have their physiological effects as secondary results. While these waves and pulses are both electric and magnetic, we may, because of the non-magnetic nature of the tissues of the body, consider only the electric effects. Every atom of the body carries electric charges. It therefore is acted on by forces as these waves or pulses pass. A few years ago we would have said that the only effect of such forces would be to increase the motion of the atom as a whole, and it is pretty well established that this would have the effect of raising its temperature or of altering its chemical relationship. Very probably the greater part of the energy of all these processes is absorbed in this way, but it does not represent the whole effect. Within the last few years, new conceptions of the atoms have been developed. It is no longer regarded as an indivisible mass of matter bearing an indivisible charge. And not merely the atom of radium and other radio-active substances must be regarded as complex, but the collateral investigations of the last few years have shown that the atoms of other substances also are not the simple bodies formerly supposed. The phenomena of

spectroscopy long foreshadowed this, but only recently have atoms been dismembered, and the separate parts studied. This work is only now at its height, and the rather large mass of observations and data has not been correlated, and is in a somewhat chaotic state. Until all the conditions are known entire consistency is not to be expected. Still, the general conception of an atom that results from these investigations is, either that the atom is a central body to which is bound one or more minute electrically charged particles called corpuscles, or that it is a cluster of such corpuscles. The mass and the electric charge of these corpuscles have been determined for a large number of gases, and have been found to be the same for all, no matter what may be the total atomic weight. The mass of a corpuscle in any gas is about one eight-hundredth part of the mass of a hydrogen atom, while the charge on the corpuscle is about equal to the charge carried by a hydrogen atom during electrolysis. When a negatively charged corpuscle is torn from the atom, and it is now known that there are a great many ways of doing this, the remainder is charged positively. The two parts thus separated are called ions, and the process of separating them is called ionization. There are a great many ways of producing ionization. Almost any violence, particularly if it be electrical, done to the atoms of a gas may tear off a corpuscle from those atoms that happen to be in a sensitive condition. Thus Röntgen rays in passing through air or any other gas ionize it. The same is true of the radiations of radio-active substances; and this ionization may be produced by either part of the radiations — the radiant charged particles or the gamma pulses in the ether.

The phenomena of ionization of gases by the three physical agents under consideration present considerable variation; some of these, although by no means all, can be explained. If we compare, for example, Röntgen rays and Finsen light, we shall find that Röntgen rays ionize air by merely passing through it, and Finsen light does not; although there is some evidence that the air is ionized by the light discovered by Schumann, this light being of shorter wave length than that employed by Finsen. Or, speaking more broadly, any gas can be ionized by Röntgen rays, while light can ionize only a few gases directly. The explanation of this discrepancy between two processes so closely allied as Röntgen rays and light is as follows: The total energy of the Röntgen rays from an ordinary bulb is very much less than that of ultraviolet light as it would ordinarily be used in an experiment. One might therefore very reasonably, at a first glance, expect less rather than greater effect. Against this is the following consideration: The number of Röntgen rays, that is to say, the number of pulses coming from the bulb, is very much less than the number of waves in the ultraviolet light; so much less indeed that the energy in each pulse may easily exceed the energy in each wave. Moreover, the pulse of the Röntgen ray, being only one ten-thousandth as long as the wave, the electrical stress exerted for equal energies in the single pulse or wave rises to an enormously greater maximum. It is on the maximum force that the separation of the ion from the atoms depends. Thus in their great maximum force the Röntgen rays have the advantage. On the other hand, light has an unquestioned advantage in its periodicity which results in a selectivity through resonance. This line of argument, if carried out, would rapidly pass beyond the limits of the present paper. The above is cited merely as an example of what must be looked for if one goes below the surface of the phenomena and beyond its empirical application.

In résumé, these three physical processes are electrical — not merely the Röntgen rays and the radiations of radioactive substances, but also the ultraviolet light. Their first effect is that of electrical violence upon the atom, which results in an increased atomic energy, and in the case of some of the atoms of partial dismemberment, and a resulting ionization. The great physiological efficiency of the Röntgen rays suggests that ionization is the more important process.

Finally, it should be pointed out that the greater part of the study of these processes has been carried out on gases, while the physician is concerned with their effects on liquid and solid substances. Some work has been done in this field, and ionization results obtained. If there is to be, corresponding to the rapidly growing physiological chemistry, a physiological physics, there lies here in the ionization of liquids a field which the pure physicist, as such, is not likely to attack for some time to come.

Medical Progress.

PROGRESS IN GASTRO-INTESTINAL DISEASES.

BY ELLIOTT P. JOSLIN, M.D., BOSTON.

FETOR EX ORE OF GASTRO-INTESTINAL ORIGIN.

Rosenheim [1] contributes an interesting and valuable article on this disease which so often baffles treatment. Usually a foul breath is due to disease in the mouth, to bad teeth, the tonsils, the nose and throat. If foci here and in the respiratory tract can be excluded, attention should be directed to the digestive tract even if no digestive disturbance is apparent. Besides the digestive tract, a foul odor to the breath may be observed in uremia and in prostatic disease accompanied by retention and decomposition of the urine in the bladder. Having excluded all such sources one systematically examines the alimentary tract.

The esophagus may be the seat of the disturbance if there is cancer or stagnation of the contents. Fetor is not, however, an invariable accompaniment. When present it is usually

[1] Die Therapie der Gegenwart, 1902, Nov., p. 483.

relieved by systematic lavage with water or disinfecting solutions.

Fetor is also uncommon in diseases of the stomach except when these are associated with disease of the mouth, *e. g.*, inflammation of the tongue and mucous membranes, swelling of the gums and irritation of the salivary glands. In such cases treatment of the mouth and teeth results in a cure, even if the lesion in the stomach persists.

Fetor may occur in catarrh, ulcer and atony of the stomach when these diseases are associated with decomposition and regurgitation of food, but this same odor may appear in a healthy person who has eructations after eating meat and fatty foods like sausage, bacon and cheese. Cancer and marked dilatation are generally accompanied by fetor, but even in advanced cancer the products of decomposition may pass on into the intestine. Here they may be rendered innocuous or be absorbed into the blood and exhaled by the lungs, thus infecting the breath.

The intestine is the most common digestive source of fetor. This is most constantly present in cancer and stenosis, less common in moderate stenosis and constipation.

The foul odor reaches the mouth usually by way of the lungs, though the gases may pass from the intestine to the stomach and there be belched. Fetor may accompany diarrhea, especially when acute indigestion is the cause, or in infectious processes associated with diarrhea, such as dysentery, tuberculosis, typhoid, more rarely in diffuse intestinal catarrh.

Rosenheim recounts several instances of fetor of intestinal origin accompanied by little subjective intestinal disturbance. The following is an example: A girl twenty years of age whose teeth and throat were pronounced healthy by specialists was troubled with fetor. She had slight constipation, but no gastric symptoms. The secretory and motor functions of the stomach were normal and the test breakfast odorless, though at the time of its removal the breath was bad. Urine normal. The stools were in hard balls, but otherwise showed no striking abnormality. An aperient water was given and a diet prescribed which contained a little white meat (chicken, fish, veal) simply prepared, milk, bread and butter, simple desserts, well cooked vegetables and fruit which were finely divided and free from skins and husks. Following this diet recovery took place in four weeks.

Another similar case is mentioned. At first the patient was put on a mixed diet; in the second period tea, red wine, meat, fish, white and black bread, and butter were given, and in the third period milk, one portion of white meat, white bread, zwieback, desserts and purée of vegetables. The fetor was least in the third period, though still manifest. The following diet was then prescribed: milk, tea, coffee, rice, macaroni, sago, nudels, simple farinaceous desserts, thoroughly baked white bread, zwieback, butter, a simple aperient water, lemonade, sweet fruit juices, sugar, the white (only) of egg, spinach, the tops of asparagus, artichokes, carrots, potato purée in small quantity. All sorts of cabbage, peas and berries were forbidden. Upon this diet the foul breath soon disappeared. Gradually the diet was enlarged by the addition of white meat one day, fish another, and finally a gradual return to a general diet was accomplished except that the meat was limited.

Rosenheim reasons from exclusion and from the effects of treatment that the fetor in these cases is of intestinal origin, and offers several hypotheses to account for it. (1) Slight changes may exist in the intestine which allow greater absorption of foul though normal products. (2) The organism may have lost its power to destroy such products. (3) An abnormally large quantity of products of normal quality may be produced.

What is the source of the products which contribute to the fetor? Clinical experience and experiment indicate the albuminous bodies. These decompose with bacteria to indol, skatol, phenol, oxyacids, ptomaines, volatile fatty acids, ammonia, sulphuretted hydrogen, methyl mercaptan, methane, hydrogen and carbonic acid,—all substances which can be excreted through the lungs.

ELECTRICITY IN DISEASES OF THE STOMACH.

Borri[2] working in Ewald's clinic upon the action of electricity on the stomach, when applied internally, summarizes his results as follows: The therapeutic advantages which can be attained by the application of the electric current within the stomach are negative as far as secretion and motility are concerned. On the other hand its action is noteworthy upon the sensibility, but only when the galvanic current is used. With the negative pole in the stomach there occurs an anesthetic action.

DYSPEPTINE IN DISEASES OF THE STOMACH.

Dyspeptine is a natural gastric juice obtained from the pig which Hepp in Paris has recently introduced into the treatment of gastric disorders. The original suggestion to use natural gastric juice therapeutically came from Pawlow, and later Hepp found that the most suitable variety was that obtained from the hog. The acidity reckoned in terms of hydrochloric acid is .2% and the dried extract 2.3%. The original preparation keeps well in the cold. Mayer reports the result of its use in v. Noorden's clinic.[3] It was given chiefly to patients with catarrh of the stomach and absent or diminished hydrochloric acid, and to cases of tuberculosis and chlorosis. The results of treatment were very favorable and manifested in decrease of subjective discomfort, increase of appetite and gain in body weight, and in some instances a return of the hydrochloric acid to normal limits. Treatment extended over five to seven weeks. Dyspeptine in 15 cc. (half ounce) doses was given during and

[2] Berl. Klin. Woch., 1904, No 26, p. 695.
[3] Die Therapie der Gegenwart, 1903, Dec., p. 541.

at the end of each meal, later simply three times a day. It was administered undiluted or disguised with essence of peppermint, lemon juice or beer.

THE DIAGNOSIS OF ULCER OF THE STOMACH BY THE DEMONSTRATION OF THE OCCULT PRESENCE OF BLOOD IN THE STOOLS.

Boas [4] calls attention to the importance in diagnosis of the demonstration of small amounts of blood in the stools. Frequently it is possible to find small quantities of blood in the stomach in ulcer, but many times it is not desirable to insert the tube for this purpose. Moreover, the insertion of the tube may easily cause slight hemorrhages even if ulcer is absent. It may be questioned whether the presence of blood in the stools can be demonstrated if the gastric hemorrhage is slight, but in answer to this are several observations which show that the ingestion of 3 cm. of blood are sufficient for this purpose.

In such examinations the presence of blood from the gums, the respiratory system and the lower intestinal tract must be excluded. In women one must avoid contamination by blood in the urine or from the genital tract.

A positive blood test in the feces, obtained under the above precautions, is obviously of much value; not enough data are as yet accumulated to demonstrate the worth of a negative test.

The method is as follows: Five to ten grams feces are reduced to the consistency of soup with water. The fat is then partially removed with 20 cm. ether, which also prevents annoying emulsions in the further course of the test. Three to five cc. glacial acetic acid are then added to the stool, the whole poured into a test tube and again extracted with ether. The addition of alcohol must be carefully avoided since alcohol alone will color the guaiac turpentine mixture blue. A few kernels of well pulverized guaiac resin are then added to the ether, carefully shaken, and then twenty to thirty drops old oil of turpentine poured in. After a little shaking, on setting aside there gradually forms a violet color, even deepening to blue, which becomes more striking on the addition of chloroform. Since the blue color is frequently confused with brown shades, it is well to control it by another test suggested by Klunge and by Schaer and controlled by Rossel. Instead of guaiac they use aloin. A knife point full of aloin is placed in a test tube and 3-5 cm. of 60–70% alcohol added and gently shaken. Ten to fifteen drops of this freshly prepared mixture, when added to the acetic acid ethereal extract of feces containing 20–30 drops of turpentine, give a bright red color in the presence of blood, and on standing acquire a pretty constant cherry red color. If there is no blood, the aloin reddens the fluid a delicate rose red, at the earliest in one or two hours and later turns to a yellow. Twenty-five to thirty drops of hydrogen peroxide can be substituted for the turpentine.

A GASTRIC PHENOMENON IN MIGRAINE AND EPILEPSY.

Mangelsdorf [5] some ten years ago observed that the stomach of one of his patients was much larger during an attack of migraine than on the preceding day. Since then he has repeatedly confirmed his first observation and more carefully studied the phenomenon. As the result of frequent attacks of migraine with the accompanying dilatation and contraction he considers that the tone of the stomach is gradually permanently altered. Atony ensues which finally leads to gastric and intestinal disturbance. The author shows schematically the increase in the vertical diameter which occurs during an attack of migraine, and how this changes as the tone of the stomach improves under appropriate treatment. The difference in size is less marked in the advanced cases, because the stomach is then already much enlarged. When the stomach is nearer normal size in the free intervals, as in the early cases, the effect of an attack is most striking.

Mangelsdorf examined 409 of 469 cases of migraine which have come under his observation, and in all but one the stomach was abnormal. In idiopathic epilepsy the same phenomenon has been noted by Mangelsdorf. In a later publication he will consider the subject more in detail.

PEGNIN.

Sigel [6] in Ewald's clinic has made use of pegnin, a rennet ferment combined with milk sugar, to make milk more readily digestible. This powder was first described by von Dungern. By its action the milk is said to be precipitated in as fine curds as human milk with the addition of rennet.

The preparation of the milk is simple. The milk is boiled in a glass flask for half an hour, then cooled to 90° F. and a tablespoonful of pegnin added to each liter. After a few minutes the milk curdles. The milk thus curdled is then vigorously shaken until the flocs have disappeared. The milk is then ready for use; it should not, however, be further heated.

The taste and nutritive value are not disturbed by this process. Sigel reports that while others have employed this milk with children, he has used it chiefly with adults, and especially with those suffering from gastric disease in which there is a diminished secretion of rennet, — chronic gastritis, achylia gastrica. It was further used in those patients who might suffer from the irritation of coarse curds, notably cases of gastric neurosis and gastric ulcer. A large number of ulcer cases were fed, after the period of rectal nutrition was completed, almost exclusively with this milk. In these various classes of patients the milk was taken gladly almost without exception and was well borne. Sigel, therefore, would heartily recommend the use of pegnin.

Reports of Societies.

AMERICAN SURGICAL ASSOCIATION.

PROCEEDINGS OF THE TWENTY-FIFTH ANNUAL MEETING, HELD IN ST. LOUIS, JUNE 14, 15, 16 AND 17, 1904.

THE Association met in the Assembly Hall of the Board of Education under the presidency of DR. N. P. DANDRIDGE of Cincinnati, Ohio.

PRESIDENT'S ADDRESS.

PRESIDENT DANDRIDGE departed somewhat from the practice of his predecessors, and instead of bringing before the Association some medical topic based on his own work, or attempting a discussion of some subject of active interest, he took the members to the backwoods, and interested them in the life and exploits of a pioneer doctor. He depicted a man of high scientific attainments and true culture, with all the elements of character which become the doctor and the man. He gave an exhaustive sketch of Antoine Francois Saugrain de Vigni, who was born in Paris Feb. 17, 1763. He came from a long line of librarians, booksellers and printers, who, as far back as Charles IX in Lyons and Henry of Navarre, had served the royal family of France. His knowledge of mineralogy made his advice often called for in the development of the mines in the Ohio valley. In the wilderness he supplied himself with ink from a natural chalybeate water and an infusion of white oak bark, and when in need of a fire, lighted it from a lens made by two water crystals with clear water between. Dr. Saugrain gave notice of the first vaccine matter brought to St. Louis, and indigent persons were vaccinated gratuitously. He practised in St. Louis till his death, in 1820. He must have been eminently successful, for he left a large landed estate for the support of his wife and six children. His scientific work lives in tradition, and has gained for him the title of the "First Scientist of the Mississippi Valley."

WHAT ARE THE MINIMUM REQUIREMENTS FOR ASEPTIC SURGICAL OPERATIONS IN HOSPITALS WHERE THE SURGEON IS ASSISTED BY A LARGE STAFF OF INTERNES AND BY NURSES FROM A TRAINING SCHOOL?

This subject was discussed with great detail by DR. GEORGE H. MONKS of Boston, Mass.

MINIMUM REQUIREMENTS FOR ASEPTIC OPERATING IN A HOSPITAL IN WHICH THE PERSONNEL OF THE OPERATING ROOM IS PERMANENT.

DR. A. J. OCHSNER of Chicago, in a paper on this subject, pointed out the fact that with a permanent personnel a definite system could be developed, which was most satisfactory, because the observations which suggested changes, as well as those which confirmed satisfactory methods, could be carried through a large, continuous series of cases under unchanged external conditions.

Stress was laid upon the importance of simplicity in the methods chosen. The less that was done in any given case, the slighter was the likelihood of doing harmful things. There should be uniformity in carrying out a plan of work, in order that every one connected with the system might know what had been done and what was to be done by the other members of the personnel in any given case. Above all things, the methods should be reasonable in their details. This would make the work more attractive, and consequently more satisfactory to those engaged in its prosecution.

The author then gave a detailed account of the system followed by him and his assistants at the Augustana hospital, where he had had an opportunity to develop uniform methods with permanent conditions during a period of fifteen years. The system comprised disinfection of patient, operator, assistants' and nurses' hands, instruments, silk, silkworm gut, horsehair, drainage tubes, hand brushes, dressings, implements, towels, sheets, etc.

The author also discussed drainage and irrigation.

Stress was laid particularly upon the danger arising from tying sutures too tightly, thus causing pressure necrosis, which favored the development of micro-organisms accidentally introduced.

The method of selecting assistants and nurses was described, and a table illustrating the manner in which each assistant recorded the progress of the wounds under his care was appended.

DR. CHARLES HARRINGTON of Boston, Mass., read a paper, by invitation, in which he detailed his studies in asepsis.

These three papers were discussed jointly.

DR. DE FOREST WILLARD of Philadelphia said that surgeons who had to deal with the practical side of asepsis in surgical operations knew that their results satisfied them to a certain degree, but it must be confessed that they had failures, and it was very essential to know whether the failures were due to the method or methods employed, or whether there were difficulties which could not be overcome. Difficulties would beset surgeons, but the question resolved itself largely into one of extreme care on the part of every one, from the surgeon down to the lowest assistant, who had the materials in charge or in preparation. There could be no doubt that a hospital which had permanent assistants, permanent nurses, was the one that was likely to secure the best results from operative procedures on the patients under its care.

DR. CHARLES B. NANCREDE of Ann Arbor, Mich., emphasized two important points, one of which was inhibition, and the other tissue resistance. A germ might be inhibited to the point that would render it safe in a given wound.

DR. JOHN E. OWENS of Chicago stated that different results were reported by different surgeons after using the same methods, and he had often wondered whether some of them might not have been due largely to the habits of surgeons.

So far as the disinfection of hands was concerned, a few years ago he was compelled to stop the use of corrosive sublimate on account of the condition of his hands, and since then he had been scrubbing them thoroughly with soap and water, keeping the nails of the fingers pared down, and afterwards washing the hands with salt solution and alcohol, and he thought his results were as good in hospital work as where other chemicals for sterilization were used.

DR. W. W. KEEN of Philadelphia spoke of his own method and the results which he had obtained by some experiments. He had adopted for several years past for the cleansing of his hands a method which was first directed to the attention of the profession by Weir, namely, the use of chloride of lime and carbonate of soda. The hands were washed thoroughly with soap and water, and in order to do this, he had in his own private hospital and at the clinic at Jefferson, little egg boilers, which were practically hour-glasses or sand-glasses that were reversible. These were marked "Soft-boiled," "Well done" and "Hard boiled." Soft-boiled corresponded to about three minutes; well done, five minutes, and hard-boiled, seven minutes. He told his assistants that when they had scrubbed their hands until the sand had reached "well done,"

good and faithful servant, they should stop. Every person who took an active part in his clinic had a culture taken from under the thumb, or one or two finger nails, particularly at the root of the nail, and from the free surface of the skin. During the last winter there were 213 cultures made, from the hands of himself and his assistants, in the clinic at Jefferson. Of this number, there were only 3 cases in which any culture was obtained. This made practically a sterility of 97% and an infection of about 3%. There was but one person who was free at every clinic, and that was the head nurse, who was a permanent official in the operating room. All the other nurses, and all the assistants, except his principal assistant, changed every three months.

He thought the method of keeping such a record of every person's hands served an admirable purpose by creating a sort of rivalry among those who were endeavoring to have clean hands before operation, and it was more to prophylaxis in preventing infection than in the results obtained that he attributed the value of the method.

Dr. W. B. Coley of New York did not believe sufficient stress had been laid upon sterilization of the skin, and although some authorities maintained it could be done properly in a few moments before operation, his experiments showed that with careful preparation the day before operation, in addition to what was done on the day of operation, sterilization of the skin even then could not be said to be perfect. In 250 cases in which he had examined portions of the skin or Reverdin grafts, taken from the field of operation immediately before, 25, or 9%, of the cases showed all kinds of cultures, some of them being staphylococcus and streptococcus. The only case of suppuration in two hundred cases showed a pure culture of the streptococcus. Carefully sterilizing the hands, using tincture of green soap, applied carefully, brushing and hot water, then washing thoroughly with 95% alcohol, with the use of rubber gloves, would give as good results as any of the measures which rendered the hands very hard.

With reference to primary union, an important element in aseptic surgery was to guard against the bruising of tissues.

A CLINICAL REVIEW OF FORTY-SIX OPERATIVE CASES OF DUODENAL ULCER.

This was the title of a joint paper by Dr. Christopher Graham and Dr. William J. Mayo of Rochester, Minn.

The authors stated that a careful history was of prime importance. The leading symptoms in the forty-six cases reported were, first, pain, which might be due to peritonitis, distention from gas formation, pyloric spasm, and the irritation of acid gastric contents on open ulcer. The pain might come on in colics or last for some hours. Second, vomiting, principally of sour, bitter liquids, or, if obstruction supervened, of food after varying intervals. Third, gastric insufficiency from interference with drainage. There was usually hyperacidity of gastric contents, constipation, and a great desire for food, although the patient reduced the diet and ate often a small quantity, but might fail to get relief sometimes obtained in gastric ulcer proper. In latent cases, evidences of blood in the fecal movements might be the only sign. Differential diagnosis from pyloric ulcer in some cases might be impossible. A considerable number of cases closely resembled gallstone disease, and differentiation often could not be made. Such an error in diagnosis did not militate against the clinician, as both conditions were purely surgical, and the differentiation in many cases must be made on the operating table. During the past eighteen months 27% of their operative gastric and duodenal ulcers involved the duodenum in combination — 53.33%. There were 33 males and 13 females; in 43 out of 46 cases the ulcer was easily detected upon abdominal exploration as a thick, white, scar-like area. Liability of duodenal ulcer to perforate was greater than gastric, but more often safely protected by adhesions. Relatively sterile contents was also favorable. In all cases the ulcer was situated in the first two and one-half inches below the pylorus, and entirely above the entrance of the common duct of liver and pancreas, with its alkaline secretion, showing the effect of the gastric juices on the duodenal wall. In all doubtful cases of differentiation between duodenal ulcer, pyloric ulcer and gallstones, the authors recommended making an incision through the right rectus muscle one inch to the right of the median line. Gastro-enterostomy best met the indications, in that it diverted the gastric contents. In acute perforation, suture was recommended, with suprapubic drainage, with after-treatment, and exaggerated Fowler's position, sitting posture.

The 46 cases were divided into 5 groups: (1) Acute perforation of chronic ulcer, 4 cases, 2 deaths. (2) Acute hemorrhage in chronic ulcer, 1 case, 1 death. (3) Duodenal ulcer with gastric complications, 25 cases, 1 death. (4) Duodenal ulcer, with gall-bladder and liver complications, usually due to adhesions from chronic peritonitis, 9 cases, 1 re-operation, no deaths. (5) Eight cases, chronic pain and distress with debility, no deaths. Total, 47 operations, 46 cases,— five operations for acute conditions, with 3 deaths; 42 operations for chronic conditions, with 1 death.

Dr. E. Wyllys Andrews of Chicago had seen in the last year or two several cases in which a marked hyperplasia, patches of exudate, with thickening of the wall of the duodenum, ulceration of the first inch and a half of the duodenum connected with a similar condition of the pylorus, had produced such a degree of massive thickening that clinically at the time of operation it was indistinguishable from carcinoma. In one such case the operation, which was a McGraw elastic ligature gastro-enterostomy, left him in a dissatisfied state of mind, as he feared he should have done a more radical extirpation, and yet in this particular case it was his fortune to do a second operation for obstruction a year after the first operation, and he found, very much to his surprise, absolute disappearance of the thickened massive wall which had formed in the first place and simulated carcinoma. This was what Mayo himself called attention to, namely, when the obstruction was relieved, when the flow was permitted from some other point, the inflammation, or ulceration, at any rate, the hyperplasia disappeared at the point of irritation, and secondary to this again, when obstruction had been relieved by drainage below, the drainage below ceased to act, and again the opening became closed, so that the surgeon had to do sometimes a second gastro-enterostomy.

Dr. John B. Murphy of Chicago said the practical lesson the paper taught was the frequency of occurrence of duodenal ulcer; that it was not recognized, and that it was not differentiated from gastric ulcer or gall-bladder disease, whether it was of infective or of stone origin.

Dr. Alexander Hugh Ferguson of Chicago asked Dr. Mayo if he had outlined for himself the class of cases in which he would do a posterior gastro-enterostomy; also the class of cases in which he would do gastrojejunostomy or Finney's operation.

The speaker mentioned one case in which he did a

pylorectomy, removing the end of the pylorus and a portion of the duodenum, with an excellent result.

Dr. MAYO, in closing the discussion, and in replying to the remarks of Dr. Ferguson, said he did not know that they had ever tried to excise any of these ulcers excepting in connection with Finney's operation. They were irregular and thick; they led to large vessels, close to the common duct, and it was difficult to get a good stump. He thought the best thing to do was to make a gastro-enterostomy, which would afford, at least, temporary relief, but the gastro-enterostomy opening was very likely to contract, so that food would, after a time, continue to pass down over the duodenal ulcerated surface, and sometimes these patients would return for a second operation.

Dr. GEORGE BEN JOHNSTON of Richmond, Va., detailed seven cases of complete removal of the shaft of the tibia, with restoration of the bone.

In the discussion, Dr. DE FOREST WILLARD said it was greatly to be regretted that not only the family physician, but many surgeons, treated such cases as Dr. Johnston had reported, for rheumatism, when there was really no sign of that disease, and they were from the beginning cases of acute suppurative osteomyelitis. Then came the septic symptoms. The physician treated them for typhoid fever and other conditions, until they drifted into the hands of surgeons, with bones absolutely destroyed, the majority of them crippled for life, with deformity of the legs. These cases from their incipiency were virulent in type, and the only time for treatment was forty-eight hours after the onset, and the quicker the surgeon got inside the bone, the better. If cases of appendicitis demanded early operation, surely it was doubly important that cases of acute osteomyelitis should be diagnosed and operated upon early.

Dr. A. J. OCHSNER stated that in a large proportion of cases in which the shaft of the bone was entirely loose, when the periosteum was incised, if the bone was left in place, there would be a regeneration of a considerable portion of the apparently dead bone. If one took such cases as had been described, made an incision which extended from one end of the bone to the other, split the entire periosteum, made it necessary for the flow of lymph to be away from the tissues, left bone there as a bone graft, he had found in a considerable number of cases that there would be a regeneration of a large portion of this bone.

Dr. JOHN COLLINS WARREN of Boston said the subject was one that should be thoroughly discussed, and a message given to the profession to realize the importance of this septic process, so that cases of acute osteomyelitis might be sent to surgeons early and treated properly.

As to treatment, the great point was to prevent the spread of sepsis. This might be accomplished by trephining the bone, by proper disinfection, by a comparatively moderate operation, or it might be necessary in certain cases to do quite a radical operation.

Dr. P. S. CONNOR of Cincinnati, O., said that in some of these cases the disease originated superficially. The cases were uniformly mistaken for erysipelas. The redness of the overlying skin was taken as an indication of the existence of the disease. Then, we had a condition simulating typhoid fever after the disease had existed for a considerable length of time, or rheumatism for a while, then typhoid fever, when the condition did not subside. Early boring of the lower end of the tibia would put a stop to the trouble. A moderate incision would not infrequently end the trouble if boring did not.

Dr. S. H. WEEKS of Portland, Me., said that while many of these cases began as a periostitis, requiring a simple incision down upon the bone, there were many others which commenced as an acute osteomyelitis in the medullary canal, and he believed under such circumstances, when an incision was made down to the bone, there should be an opening made into the medullary canal, and that canal drained.

(To be continued.)

THE RHODE ISLAND MEDICAL SOCIETY.

THE ninety-third annual meeting of the society was held in Masonic Building, Providence, on Thursday, June 2.

The House of Delegates met for the first time. There were present: Drs. Wm. R. White, President; S. A. Welch, Secretary; Horace G. Miller, Geo. D. Hersey, F. B. Fuller, John Champlin, G. T. Swarts, F. E. Burdick, W. A. Risk, Julian A. Chase and W. E. Wilson.

A letter was read from Dr. Frederick Holme Wiggin, urging the passage of resolutions in favor of a national incorporation for the American Medical Association. After discussion it was voted not to instruct the national delegate in this matter.

Dr. WHITE called attention to the discrimination in railroad rates against New England. From the west and central portions of the country the rate for delegate is one fare and a dollar; from New England it is one fare and a third.

Dr. CHAMPLIN said that the attention of the proper committee of the American Medical Association would be called to this matter.

The general session was opened at 11.30 A.M., by the President, Dr. Wm. R. White.

Dr. GEO. S. MATHEWS reported for the trustees of the Chase Wiggin Fund that one meeting had been held and a plan of work outlined.

Dr. WM. R. WHITE reported for the trustees of the Fiske Fund that the prize of $250 offered last year for the best essay on the subject, "The Action of Light as a Therapeutic Agent," had been awarded to Dr. Leonard Keene Hirshberg of Johns Hopkins University, Baltimore, Md. The coming year a prize of $250 is offered for the best essay on the subject, "The Sequelæ of Gonorrhea in Both Sexes."

Announcement was made of the deaths of Dr. Elisha P. Clarke at Hope Valley, March 17, 1904, of tuberculosis, and of Dr. Charles D. Wiggin at Mystic, Conn., on May 21, 1904, of pneumonia. Dr. White said that Dr. Clarke was formerly an honored president of the society and of great influence in the town in which he lived, an influence professional, mercantile and social.

Dr. George M. Crowell, formerly of Pawtucket, has become a non-resident member and settled in New Canaan, N. H.

The following physicians have joined the society since the last meeting;

From the Newport Medical Society, Drs. Alexander J. Anderson and Wm. A. Sherman of Newport, Dr. Floyd W. Rogers of Tiverton and Dr. Berton W. Storrs of Portsmouth.

From the Providence Medical Association, Drs. Joseph C. O'Connell, Clinton S. Westcott, Frederick G. Phillips, George S. Hathaway and Remington P. Capwell, all of Providence.

Dr. Wm. J. McCaw was appointed delegate to the commencement of the Rhode Island College of Pharmacy and Allied Sciences.

As delegates, were presented from the Massachusetts Medical Society, Dr. Grace Wolcott; from the New Hampshire Medical Society, Dr. Oscar Young, and from the Vermont State Medical Society, Dr. H. Edwin Lewis.

Dr. Lewis said that in the last two years the Vermont Society had reorganized, with twelve county societies. They had made progress in legislating for reciprocity with other state societies. They had recently secured a commission to investigate tuberculosis. Dr. Young of New Hampshire spoke of the successful meeting which their society had recently held. Their last legislature passed a bill for a free home for consumptives, but the governor vetoed the bill.

Dr. Wm. J. Burge presented an old picture of Dr. Isaac Senter, which he had found in Wickford on the wall in the old Shaw Homestead. Dr. Hersey, in his annual address,[1] spoke of Dr. Isaac Senter as a native of colonial New Hampshire who came to Newport in early life to study medicine with Dr. Thomas Moffatt, a noted Tory and librarian of the Redwood Library from 1750 to 1753. Later Dr. Senter was surgeon in the ill-fated Arnold expedition to Quebec, where he was taken prisoner. On his release he settled in Pawtuxet and later in Newport, where he acquired a high reputation. He was the earliest writer of note among Rhode Island physicians. A portion of his valuable library has come down to us through Dr. David King, late of Newport. Dr. Burge said that Dr. Senter was his grandfather's family physician.

Dr. James L. Wheaton, Jr., of Pawtucket, read a paper entitled "Colica Mucosa and Its Treatment." An abstract of which is as follows:

Until recently it has been difficult to characterize or classify this disease. One group of writers, including Einhorn, Boas, Ebstein, and Schutz, concede the rôle of inflammatory processes in the genesis of the majority if not all of the cases of this affection.

A second group, headed by Nothnagel, believe that there are two forms of the disease, one with and one without inflammatory phenomena, and they separate the two forms, calling one enteritis membranacea and the other colica mucosa, the latter only of neurotic origin.

The third group includes V. Leube, Fleischer, Hemmeter, Van Noorden and Westpfalen. The last says that the majority of cases which are accompanied by the formation of membrane are in reality secretory neuroses of the bowels. The neurosis is made responsible for the production of excessive quantities of mucus.

The mucus excreted may assume different types, loose, glairy, drier or intermediary transitions, depending upon its length of stay in the intestines. The mucus, however, is very tenacious, and in this differs from the ordinary intestinal mucus.

The etiology is a matter of various opinions. The majority of cases occur between the twentieth and forty-fifth year, and in women. All show more or less extensive neurotic or hysterical stigmata.

In almost every case the patient lives on a restricted diet and is underfed. The majority are dyspeptic or constipated. As a rule, preceding the development of the disease, the patient has been obstinately constipated for weeks or months.

The two cardinal symptoms are paroxysmal attacks of pain and the passage of smaller or larger quantities of mucus.

In treatment we consider the attack itself and its causes. For the former a narcotic and high injections, preceded or not by oil enemata, are indicated.

For the second, instead of restricted diet, it has been found best to give a very coarse diet, such as bread with a large proportion of husks, vegetables containing much cellulose, fruits with small seeds, besides large quantities of fat. This, with an occasional high enema of oil, will cure most cases and, in addition, many of the nervous phenomena.

[1] Transactions, vol. vi, p. 166.

Dr. W. Frank Morrison, of Providence, presented a paper upon, "The Harmfulness of Overeating." He said in part:

"There are great societies for the encouragement of public sentiment and of legislation opposed to alcoholic intemperance, but little is said of intemperance in eating. Only a few religious societies demand moderation in eating, and yet, while we are surprised at the endurance of these people and their capacity for work, and while we admire their fresh complexions and the placidity of their lives, they have few followers. The poor man takes pride in furnishing his family with a diet of rich and expensive articles of food, and he imagines that he is inciting them to greater health and strength.

"The amount of food eaten by the ordinary person in a day is much more than is needed."

Dr. Morrison closed his paper by saying that he thought that the treatment of people suffering from overnourishment was a matter of close observation on the part of the physician.

Dr. Wm. R. White, the president, delivered the annual address on "Some Phases of Medico-Sociology."

Dr. White closed his paper by referring to the change in the government of the society, saying: "With larger fellowship our strength and influence in our own cities and state will be recognized, and our power in matters that rationally concern us will be increased. Under the new plan much responsibility will fall on certain officers of the local societies, and you who are members of them, being loyal and true to this society and to your profession, will see to it that the right men are elected to office. To me the future of your society looks most encouraging. Remembering the good work of the past, I foresee more and better work. All that is necessary is interest and co-operation. If you older men will draw from your years of experience and observation; if you of middle age will give us the benefit of your large clinical opportunities in hospital and private practice, reporting your rare and interesting cases; if you younger men will tell us of the new things you have recently been taught in the splendid medical schools of the period; if you country doctors will tell us how you, single-handed, cope successfully with emergencies that in the city would mean from one to four consultants; if you women physicians will bring reports from your field of labor and show us men some better ways than those we fancy are the best; if you specialists will impart to us as much as you can afford to, or as you think it proper for us to know, and through us add to public safety and intelligence; if you health officials, medical examiners and school inspectors will keep in touch with us; if you who are in charge of our hospitals and institutions will inform us as to current progress in your lines of work; if, especially, you laboratory experts will report on latest discoveries that bear on diagnosis and treatment; then, I say, will the Rhode Island Medical Society show stronger reasons for its existence and support."

At the dinner which followed, Dr. Chas. V. Chapin was anniversary chairman. The speakers were the mayor, Augustus S. Miller, Prof. Wm. C. Poland of Brown University and Dr. C. V. Chapin.

Dr. Chapin, in closing the dinner exercises, said that while the specialist of modern times is a valuable member of the medical fraternity, and his great knowledge is at times almost indispensable, he hoped the time would never come when the general practitioner, who knows something about every branch of the science, would become extinct. The meeting was then declared adjourned.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 11, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

WORK AS A THERAPEUTIC MEASURE.

AMONG the many rational therapeutic measures which have been advocated of late years, small attention has been paid to the efficacy of work. Rest, exercise, massage, electricity, hydrotherapy, vibration and many other means of treatment have been tried with much enthusiasm by various persons within and without the profession. Of these, perhaps none has had so enthusiastic a following as the so-called rest treatment, introduced in systematic form by Dr. Weir Mitchell, and practised indiscriminately ever since. That the rest treatment is useful and has again and again demonstrated its usefulness in appropriate cases, we make no question. That it has been peculiarly misused is likewise not open to doubt. We venture to say, with small expectation of contradiction, that the rest cure, so-called, has been far more satisfactory in the hands of its founder than in the hands of others, however conscientiously they may have attempted to carry out the lesson which he taught. As a matter of fact, all experience goes to show that our enthusiasms in many methods of treatment often get the better of our judgment, and that discrimination is easily lost in our effort to better a difficult condition. That this undue enthusiasm is, however, a valuable, although unacknowledged, factor of the treatment must also be admitted, and with enthusiasm as such we must certainly have no quarrel.

In view, however, of all the time and attention which has been given to treatment by so-called rational methods, it is somewhat extraordinary that no systematic attempt has been made to systematize a method of treatment which shall have work, either physical or mental, as its fundamental principle. Of course, we recognize the fact that physicians are continually advising exercise, and often physical labor of a more or less definite sort, but so far as our knowledge goes, with the possible exception of Moebius, no one has mapped out a work cure in the same systematic fashion as a rest cure, for example, has been developed. We are so accustomed to consider our patients as individuals of lowered physical and mental vitality that we frequently overlook the fact that their appearance of invalidism is due to quite other causes than those for which rest and recreation could work a cure. It becomes increasingly apparent, as one's attention is directed to the matter, that overwork, as the term is popularly used, means almost nothing. It is the rarest possible experience to come in contact with a person who is really suffering from overwork as such. His hours may be long, his work may be uncongenial, and his physical strength insufficient to meet the demands placed upon it, but to generalize and say that overwork, as such, is the cause of the innumerable nervous breakdowns which are everywhere about us is no longer to be maintained. Our conviction is growing, on the other hand, that the lack of proper employment is rather the source of the various failures which are familiar to every physician. That such employment of the mind and also of the body is conducive to health cannot be questioned, and we are inclined to think that if physicians insisted upon the necessity of work with anything like the frequency that they insist upon the necessity of rest, in dealing with the so-called neurasthenic invalid, they would accomplish far more definite results. If it be true that overwork is rare, and that the moral and physical stimulus which work gives is desirable, it may hardly be questioned that a systematic treatment by work is as rational as a systematic treatment by any other means. If we could realize that many of the ills of life are due to perversions of natural processes rather than to fundamental defects, the rationality of a plan of work as opposed to a plan of recreation or rest or anything else would forthwith become apparent. We await with confidence the formulation of such a method of treatment, which shall have for its aim a building up of temporarily disordered functions through systematic effort and employment. This tendency in sporadic form we see about us everywhere, but its systematic application as a legitimate and useful therapeutic measure seems not yet to have been attained.

HEALTH AND MEDICAL LEGISLATION OF 1904 IN MASSACHUSETTS.

No session of the General Court for several years has been so barren in its results, so far as health and medical legislation is concerned, as that of the present year; and yet an abundant grist of material was introduced for discussion before several committees, in which both medical men and health officers showed an active interest. Among the topics presented in the shape of bills and petitions were the following:

To protect animals from scientific cruelty, House 174 (this bill met with its usual fate); to license barbers, House 378; to prevent premature burial (an absurd and chimerical scheme, already referred to in the JOURNAL); to prohibit fraudulent advertisement of medicines; to prohibit expectoration in public places; to revise the plumbing laws; to prohibit sales of food and drink containing deleterious substances; to prohibit the sale of cigarettes by other than licensed persons; to promote public health in theatres and places of amusement; to regulate the taking of ice; to prohibit the use of boracic acid and salicylic acid in preserving food products; for legislation on pollution of water supplies; on the registration of nurses; to regulate undertaking and embalming; for better examination of bodies before embalming; for labeling canned goods; two bills to regulate the sale of baking powders; to regulate the sale of face bleaches; to state on packages the ingredients of patent medicine; on the adulteration of vinegar; on the sale and giving away of opium; to prohibit the use of aniline dyes in food; that dog licenses may contain rules for the prevention of hydrophobia; on the powers of local boards of health; to prohibit the use of cellars and basements for bakeries.

Out of all this proposed legislation, only two or three measures were finally enacted and placed among the laws of the Commonwealth.

One of these laws (Chapter 395) gives the State Board of Charity power to remove any person "infected with a disease dangerous to the public health, and who is maintained or liable to be maintained by the Commonwealth, to any hospital provided for state paupers, or they may provide such place of reception for such person as is judged best for his accommodation, and the safety of the public."

The emergency which gave rise to this legislation was the discovery of a case of leprosy in the town of Harwich.

Another act (Chapter 445) requires the approval by the State Board of Health together with certain other authorities of the plans for the construction of a dam across the Mystic River in Medford, and also directs the Board to report to the next General Court a method for purifying the Mystic River, Alewife Brook and adjacent water courses.

Two resolves were also enacted. One of these provided for an investigation by the State Board of Health as to the business of undertaking and embalming, and the other for an investigation as to sanitary and other conditions affecting the health or safety of employees in factories and other establishments.

SHELLFISH IN POLLUTED WATERS.

CONSIDERABLE discussion has arisen within the last few years regarding the possibility of infection from contaminated shellfish taken in the neighborhood of sewage outlets. The matter has been discussed and studied at considerable length in England, with the result that a definite contamination of oysters has been demonstrated, making them a menace to health. In this state the legislature has also taken action, as the following excerpts from the revised laws show:

SECTION 113. The state board of health may examine all complaints which may be brought to its notice relative to the contamination of tidal waters and flats in this commonwealth by sewage or other causes, may determine, as nearly as may be, the bounds of such contamination, and, if necessary, mark such bounds. It may also, in writing, request the commissioners on fisheries and game to prohibit the taking from such contaminated waters and flats of any oysters, clams, quahaugs and scallops. Upon receipt of such request, said commissioners shall prohibit the taking of such shellfish from such contaminated waters or flats for such period of time as the state board of health may prescribe.

SECTION 114. Whoever takes any oysters, clams, quahaugs or scallops from tidal waters or flats from which the taking has been prohibited as provided in the preceding section shall forfeit not less than five nor more than ten dollars for the first offence, and not less than fifty nor more than one hundred dollars for each subsequent offence; but such penalties shall not be incurred until one week after the commissioners on fisheries and game shall have caused notice of such prohibition, with a description, or the bounds, of tidal waters or flats to which such prohibition applies, to be published in a newspaper published in the town or county in which or adjacent to which the tidal waters or flats to which such prohibition applies are situated.

These laws were passed in 1901, and it is under their authority that the State Board of Health has recently made an investigation of the condi-

tions existing in New Bedford, Mass., harbor. This investigation, which was prompted by the suggestion of the New Bedford Board of Health, has disclosed the fact that shellfish from the waters of certain parts of New Bedford harbor are infected. The State Board of Health has taken action prohibiting the taking of shellfish from these parts of the harbor, or from any place within three quarters of a mile of the outlet of any city sewer.

There can be no question whatsoever of the wisdom of such action, stringent as it may at first appear to be. As we have already suggested, the evidence is rapidly accumulating to show that infected shellfish are a very serious menace to public health, and that through their agency, disease, notably typhoid fever, may be spread to an alarming degree. The avoidance of this danger naturally lies in the closest possible inspection of oyster beds and other collections of shellfish used for food wherever there is a possibility of contamination through sewage. Were this done, and we have no doubt it will be done, this menace to the public health would quickly be eliminated. We are glad, therefore, to call attention to the action already taken with regard to New Bedford harbor.

MEDICAL NOTES.

CHICAGO AS A HEALTH RESORT. — According to the weekly bulletin of the Chicago Health Department, it is again insisted that Chicago is the most healthful large city on earth. It is especially the best city in which to be born, as witnessed by certain figures of the number of deaths under five years. In 1894 the proportion of deaths under five to the total number of deaths was 46.1%, whereas in 1903 it was but 28.6%. The figures show a decrease of 37.9% in the child mortality in the last decade, and for the first six months of the current year the proportion of deaths under five to the total deaths was only 24.01%, or nearly 50% lower than in 1894.

HONORS TO PHYSICIANS. — On July 16 a monument in memory of Pasteur was unveiled in Paris by President Loubet. The unveiling was attended by Mme. Pasteur and by various representatives of the government and of abstract science. It is reported that a prize in honor of Adolf Kussmaul has been founded by Professor Czerny, his son-in-law. It is intended to award the income of $2,500 every third year for the best work on therapeutics published in German during the preceding three years. Dr. Otto Kahler, formerly professor of medicine at Vienna, has been honored by the unveiling of a bust at the school of medicine.

ROCKEFELLER INSTITUTE PLANS. — According to the *Medical News* plans have been filed for the new laboratory building in New York to be erected on Exterior Street, east of Avenue A, for the Rockefeller Institute of Medical Research, of which Dr. William H. Welch, of Johns Hopkins University, is president, and Dr. S. Flexner, Resident Director. It is to be a five-story edifice, 136 x 60, with a facade of limestone and brick. It will be decorated with pilasters of brick, and have a porch entrance flanked with decorative columns for the support of the electric lights. The first floor will be an assembly hall, with a library and study and directors' room. The upper floors will contain large general and special laboratories and research rooms. The fifth will have a dining hall and living quarters, and the roof a special operating room and quarters for the animals under examination. Adjoining the main building will be a two-story building for the animals used by the doctors, and power house. The cost of the buildings is estimated at $325,000.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon Aug. 10, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 48, scarlatina 11, typhoid fever 28, measles 9, smallpox 0.

ADDITION TO BROCKTON, MASS., HOSPITAL. — It is announced that the Brockton Hospital is to have an addition at a cost of $20,000, to be devoted particularly to surgery.

BOSTON MORTALITY STATISTICS. — The deaths from diarrheal diseases and tuberculosis have been comparatively high owing to the hot weather. The total number of deaths reported to the Board of Health for the week ending Aug. 6 were 250, as against 170 the corresponding week last year, showing an increase of 80 deaths and making the death-rate for the week 21.15. The number of cases and deaths from infectious diseases was as follows: Diphtheria, 28 cases, 1 death; scarlatina, 8 cases, no deaths; typhoid fever, 26 cases, 5 deaths; measles, 17 cases, 1 death; tuberculosis, 49 cases, 25 deaths; smallpox, no cases, no deaths. The deaths from pneumonia were 16, whooping cough none, heart disease 23, bronchitis 2, marasmus 9, cholera infantum 21. There were 9 deaths from violent causes. The number

of children who died under one year was 83; under five years, 107; persons over sixty, 39; deaths in public institutions, 82.

NEW YORK.

Pathological Laboratories at Bellevue Hospital. — The announcement is made that Dr. Charles Norris of New York has received the appointment of director of the pathological laboratories of Bellevue Hospital, the appointment dating from Oct. 1, 1904.

Resignation of Dr. George F. Shrady.—The *Medical Record* of Aug. 6 announces the resignation of Dr. George F. Shrady from the editorship of the journal after a service of nearly forty years. Dr. Shrady has had editorial control of this journal from its foundation, thirty-eight years ago. Dr. Thomas L. Stedman, for many years associated with Dr. Shrady in the editorial work, now becomes editor.

Appropriations. — Urged on by an emergency message from Mayor McClellan, the Board of Aldermen on July 26 passed resolutions of the Board of Estimate and Apportionment, appropriating $5,500,000 for the Department of Education, in order that the work of the department may be continued without interruption. The mayor's letter requested the immediate passage of the resolutions because of the insufficiency of school accommodations in the city, not only in the matter of sites, but also in recreation centers, vacation schools and playgrounds, lighting facilities, and the equipment of kindergartens, cooking schools, workshops, etc. "The very apparent necessity of doing all in our power," he said, "to remedy the school situation with which we are confronted makes it unnecessary for me to impress on you further the obligations we are all under of putting at the disposition of the Board of Education the funds represented by these several appropriations." Among the other appropriations passed the same day were the following: $243,000 for the Department of Health; $100,000 for cleaning the sewers in the Borough of Manhattan; $67,000 for a new boat to run to the hospital for contagious diseases on North Brother Island, and $3,000 for the School of Agriculture in DeWitt Clinton Park.

June Mortality in New York State. — The bulletin of the State Department of Health shows that the number of deaths reported in the state during the month of June was 10,997. This is about 1,500 in excess of the average for the month in the past five years, June being uniformly in New York the month of the lowest mortality, with the exception of November. This increase in the mortality is stated to be in great part due to the marked increase in the deaths reported by New York City, which returns 1,362 deaths from accident. A large part of these was, of course, caused by the "Slocum" disaster. Of epidemic diseases, the only increase in mortality is from cerebrospinal meningitis, which became epidemic in New York City in March and reached its height in May, the deaths from it in June being about the same number as in April. Pulmonary tuberculosis caused an excessive mortality for the month of June, and this was general throughout the state. There were almost as many deaths from it as in May, and 150 more than in June, 1903. The prevalence of influenza and its allied or resultant affections, which characterized the disease movements earlier in the year, have, so far as reports of it as a principal or contributing cause of death are concerned, been largely abated. It is evident, however, the bulletin states, that its consequences have continued, and the increase in tuberculosis is attributed to it. Deaths from pneumonia and other acute respiratory diseases which more immediately accompany influenza, and which had been very high since January, were less than half as many as in the month of May.

Reunion of Incubator Babies. — There was recently held at Coney Island a reunion of incubator "graduates," where no less than forty healthy infants and young children were present. Notable among them were the Cohen triplets, who were born in a New York tenement house in July, 1901, weighing together at the time only as much as one baby of ordinary size, and who, during the rest of the summer, attracted much attention at the Pan-American Exposition in Buffalo. Dr. Edward Wallace Lee of New York, who with Dr. M. A. Couney of Berlin, the inventor of the incubators employed, installed the system first at the Omaha Exposition in 1897, gave some interesting statistics. He stated that whereas about 97% of the class of infants now reared in incubators formerly died, there had been lost but six out of 56 incubator babies at the Pan-American Exposition, four out of 32 at Coney Island in the summer of 1903, and three out of 38 during the present season. In this year's incubator colony at Coney Island there are three sets of twins and one of triplets.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JULY 30, 1904.

CITIES.	Population Estimated, 1904.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from: Infectious diseases.	Acute lung diseases.	Diphtheria and croup.	Typhoid Fever.	Diarrheal Diseases.
New York	3,908,644	1,520	709	45.00	5.72	1.58	.85	28.02

Deaths reported, 3,546; under five years of age, 1,531; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,468; acute lung diseases 204, consumption 345, scarlet fever 14, whooping cough 14, cerebrospinal meningitis 31, smallpox —, erysipelas 3, puerperal fever 5, measles 16, typhoid fever 50, diarrheal diseases 949, diphtheria and croup 41.

From whooping cough, New York 3, Chicago 5, Philadelphia 2, Pittsburg 2, Boston 1, Melrose 1. From measles, New York 8, Chicago 1, Philadelphia 3, Boston 2, Lowell 1, Chelsea 1. From scarlet fever New York 8, Chicago 2, Baltimore 2, Pittsburg 1, Lowell 1. From cerebrospinal meningitis, New York 25, Boston 3, Lynn 2, Marlborough 1. From erysipelas, New York 2, Taunton 1. From typhoid fever, New York 13, Chicago 9, Philadelphia 9, Baltimore 6, Pittsburg 10, Boston 2, Lowell 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending July 16, the death-rate was 13.7. Deaths reported 4,019; acute diseases of the respiratory organs (London) 62, whooping cough 92, diphtheria 37, measles 142, smallpox 5, scarlet fever 28.

The death-rate ranged from 4.8 in Bournemouth, to 26.2 in Bootle; London 12.9, West Ham 12.7, Brighton 13.6, Southampton 13.4, Plymouth 16.0, Bristol 11.5, Leicester 10.5, Nottingham 13.6, Liverpool 19.6, Bolton 8.9, Manchester 16.4, Salford 18.7, Bradford 15.2, Leeds 14.8, Hull 15.6, Sheffield 14.0, Cardiff 12.1, Rhondda 21.3, Wigan 14.1, Merthyr Tydfil 17.2, Hornsey 5.8, Huddersfield 22.5.

METEOROLOGICAL RECORD.

For the week ending July 30, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING AUGUST 4, 1904.

PURVIANCE, GEO., assistant surgeon general. Granted extension of leave of absence from June 20 to June 30, inclusive. July 30, 1904.

BANKS, C. E., surgeon. Granted leave of absence for one month and fifteen days from August 12. July 29, 1904.

SPRAGUE, E. K., passed assistant surgeon. To report to Surgeon G. W. Stoner, Immigration Depot, New York, for duty. July 29, 1904.

GREENE, J. B., passed assistant surgeon. Upon the return of Assistant Surgeon H. McG. Robertson, relieved from duty at New York (Stapleton) and directed to proceed to Fort Stanton as inspector of unserviceable property. Upon completion of this duty to remain at Fort Stanton and await further orders. July 30, 1904.

LAVINDER, C. H., passed assistant surgeon. Relieved from duty at Delaware Breakwater Quarantine, and directed to proceed to New York (Stapleton) and report to medical officer in command for duty and assignment to quarters. August 1, 1904.

FOSTER, M. H., passed assistant surgeon. Granted leave of absence for fourteen days. August 4, 1904.

TROTTER, F. E., assistant surgeon. Granted leave of absence for ten days from August 5. August 4, 1904.

BAHRENBURG, L. P. H., assistant surgeon. To assume command of service at Delaware Breakwater Quarantine, relieving Passed Assistant Surgeon C. H. Lavinder. August 1, 1904.

SALMON, T. W., assistant surgeon. Granted leave of absence for seven days from August 2, 1904, under paragraph 191 of the regulations.

PORTER, J. Y., sanitary inspector. To proceed to Havana, Cuba, for special temporary duty, and to inspect the disinfecting steamer "Sanator." July 27, 1904.

BRICE, J. W., acting assistant surgeon. Granted leave of absence for thirty days from September 20. July 29, 1904.

FOSTER, J. P. C., acting assistant surgeon. Granted leave of absence for thirty days from August 1. August 1, 1904.

STUART, A. F., acting assistant surgeon. Department letter of June 22, granting Acting Assistant Surgeon Stuart leave of absence for thirty days from July 1, amended to read twenty-one days. August 1, 1904.

ROGERS, EDWARD, pharmacist. Granted leave of absence for sixteen days from August 5. July 28, 1904.

TROXLER, R. F., pharmacist. Granted leave of absence for thirty days from September 5. August 1, 1904.

NEVES, GEO., pharmacist. Granted leave of absence for thirty days from August 27. August 1, 1904.

BOARD CONVENED.

Board convened to meet at Port Townsend, Washington, D.C., for the physical examination of candidates for second assistant engineer in the Revenue Cutter Service. Detail for the board: Passed Assistant Surgeon J. H. Oakley, Chairman. Acting Assistant Surgeon W. E. Patrie, Recorder.

PROMOTIONS.

T. B. MCCLINTIC, JOSEPH GOLDBERGER and W. A. KORN, assistant surgeons. Commissioned (recess) as passed assistant surgeons to rank as such from July 28, July 27 and July 27, 1904, respectively. July 27, 1904.

Original Articles.

MIND CURES FROM THE STANDPOINT OF THE GENERAL PRACTITIONER.*

BY ROBERT T. EDES, M.D., READING.

If one wished to ascertain the general trend of opinion in the community relative to the progress of medicine in recent years, and with this object in view were to glance over the table of contents of a large number of medical journals from cover to cover, he might infer that leaving out surgery and obstetrics there was a sort of polarization going on in which one set of opinions grouped themselves around mental, psychical, and even miracle cures, as represented by all sorts of 'pathies, 'ologies and sects, religious and otherwise, and at the other extreme around a condition of polypharmacy such as the world has never before seen; where if we believe half of what we read on one side the wonder is that any one dies, if at all, before he reaches one hundred; or, if we believe another set of writers, that any one ever lives to grow up.

It may seem absurd, or at least disrespectful, to suppose that The Massachusetts Medical Society goes to either of these extremes. As a matter of fact I don't think it does,— not as a society,— but a little experience showed me that one of these poles is not without its attractions for some of the members, and it is not an unfair inference that the other is drawing to itself some adherents by the fact that such a subject as that upon which I have been asked to say a few words finds a place upon the programme.

I had occasion to send to a good many of the Fellows some years ago a circular letter of inquiry as to the drugs which it was thought desirable to reject as useless from the U. S. Pharmacopeia, and what should be added. I received some answers somewhat as follows: "What is the use of putting in a lot of trash such as is now there? Give us something practical and useful."

Then would follow a list in which the influence chiefly to be noticed was evidently the latest advertising pages in the Journals. When one looks over pharmacopeias and works on therapeutics (and by the way I know of little more instructive reading on the subject than Stillé's "Materia Medica" compiled when the learned author was a young man, studied side by side with the last edition of the "American Dispensatory" of which the therapeutic part was written by the same author after many years of evidently well digested experience), and if he notes the changing lists of drugs which have, many of them, been vaunted just as highly and on apparently the same basis as those now produced in such bewildering rapidity by the coal-tar chemists, and when he recalls the varied and often contradictory theories which have controlled the practice of medicine, many of them being, according to our present knowledge of pathology, absolutely groundless, he is obliged to acknowledge the vigor of the *vis medicatrix naturæ*.

But when we find that in spite of mistakes and contradictions, which the critics and satirists are not slow to perceive nor reluctant to remind us of, that the physician is still sought for in sickness as a helper and not merely as a sort of sanitary adviser, in order to promote recovery or at least to witness it, we have evidently to reckon with some kind of constant and permanent usefulness which has comparatively little to do with therapeutics as laid down in books, but which has been a part of the physician's *armentarium* ever since there were physicians.

This moral support or encouragement, the relief from responsibility, the substitution of decision for doubt, even a masterly inactivity when there are no active steps to be taken, has long been recognized by the laity and by those literateurs who are fond of doctors but not of drugs, although it is apt to be somewhat slightingly spoken of by those who want something to be done promptly.

We are all familiar with the story, which I presume continues to go down from one generation to the next, and which in one form or another is told to us by gentlemen of other professions who wish to pat us physicians on the back on public occasions, of the doctor's smile which was supposed to be worth so many hundreds or thousands per annum, according to the social stratum to which he administered. The market for this commodity, however, varies greatly. While a lady fatigued with what she is pleased to term her social duties may be very willing to pay quite a liberal fee for his smile to the fashionable practitioner who "does not believe in drugging," which is the proper name to apply to the administration of all medicines except those which *you* happen to fancy, and which does *not* exclude in the case supposed "just a little sleeping powder" or "just an occasional nerve tonic," there are others who begrudge even a small one for the moral support of an equally competent physician unless they get something with it which they can taste or feel. But this sort of comfort is hardly therapeutics in the strict sense, and it certainly does not work wonderful cures. If there are any, they are discounted in advance and supposed to be in the ordinary way of business, unless perhaps they find commendation in the doctor's obituary.

Considering the very prominent position which psychic treatment in one form or another occupies in the public mind and the extravagant claims made for it, and hence its necessary importance in the professional consciousness, it is worth while to consider what morbid processes can be beneficially affected by mental action. Of course we do not expect or admit any influence of outside or foreign mind or spirit or nerve function upon the bodily processes of any patient except through that patient's own mind or emotions. If any such be possible it is the nature of a miracle and does not come within the scope of human physiology.

*Read before The Massachusetts Medical Society, June 8, 1904.

"Christian Science" is so far correct that it refers its therapeutic action to the mind of the patient, stimulated of course by its meaningless phraseology and fantastic doctrines, which to a certain kind of intelligence appeal so much more strongly than either scientific reasoning or old-fashioned Christianity.

In an extremely philosophical and suggestive work ("Anglo-Saxons and Others," by Aline Gorren), which I saw for the first time after this paper was written and in part read, I find so excellent a statement of the mental attitude of a large part of our community that I cannot forbear quoting it:

> The habit of action and attention to the realities have drawn away the mind from the field where the highest criticism of life is achieved, and the mental processes which such criticism calls into play are stiff from disuse. Human reason was told to act, to test all things for itself, to take no one's word for it, at the Reformation. But as a stimulant to its activity in the realms of abstract thought the Reformation was a failure. M. Guizot but observed what many others have seen when he wrote that in all Reformed countries something was lacking to the perfect organization of intellectual society, and to the free circulation of general ideas.
>
> And here, by the way, is to be found the cause of all that vague, inconsequent, metaphysical yearning which, with apparent contradiction, runs like a vein in a rock up through the solid unspeculativeness of the Saxon nature. Nowhere are there so many persons of sound intelligence in all practical affairs so easily led to follow after crazy seers and seeresses, and after new "psychic" doctrines of every known and unknown degree of wildness, as in England and the United States. The tenets of the Russian religious sects are at least free from the pseudo-scientific pretensions which constitute the chief absurdity of American and English metaphysical churches, healing societies, and the like.
>
> The truth is that the mind of man refuses to be shut out absolutely from the world of the higher abstractions, and that, if it may not make its way thither under proper guidance, it will set off even at the tail of the first ragged street procession that passes. If no habit has formed of making discriminations, of separating the genuine from the false, there will be sad mistakes made, evidently. And we shall continue to see business men not to be "taken" in by the sharpest in the management of their daily interests, not to be deceived in the quality of any material goods offered to them, sitting, ingenuous and receptive, under the jargon of some foolish woman with claim to a newly revealed cure for all the ills of the body and the soul.
>
> And the upshot? — In the aggregate, with all his lack of critical faculty, no harm comes to this order of man. His brain, as to the abstractions, is never clear, is always in a fog; but he works, and he fights if need be, and he goes on without ceasing in the thing which he has undertaken and he succeeds. He succeeds because he never questions that he is right all through, and takes much of his proof on faith.
>
> Who cannot feel the power that goes out from such a mental stand as this? A rationalistic, modern Frenchman, debating his motives, cynical as to his virtues, philosophizing his own errors, doubts and is lost.
>
> This newer type of man does not debate, is by no means doubtful of his own virtue, and never philosophizes, not finding it easy work. And he is invulnerable, and everything goes down before him.
>
> That trait of his which is called hypocrisy, but which is not hypocrisy, only a confusion of ideas and feelings, is the direct cause of one half of his impressiveness. The day on which he loses it will be a day of disaster.

What are the real physiological or pathological processes over which mental action, intellectual or emotional, can be supposed to have any effect?

There are certain ones covering a very wide field in the ordinary practice of medicine in which there is no satisfactory evidence of any such direct influence at all.

Fever, which is so important an element in pathology, especially of acute diseases, and a very large number of chronic infectious ones, is apparently uninfluenced. In the novel, to be sure, the mother, or the very old and wise physician, or the good "sister," or the pretty nurse, lays her hand upon the heated brow of the hero and his fever subsides. The so-called "fever of excitement," or "anger," over-excitement of any kind, may undoubtedly be controlled by reason, but there is not the least ground for supposing that the pyrexia of the pathologist, marked by a rise of temperature, an increased secretion of solids, and usually dependent upon a more rapid metamorphosis of tissue, is influenced in any important way by mental action, except so far as rest promotes and excitement hinders the normal processes of defervescence.

And yet in its early stages fever is to a large extent an affair of nerves. It can be reduced by baths and by various drugs. Why not by the determination of the patient or the spell of the faith curist? Simply because it is not. Over many processes of nutrition there is little influence for the worse and none at all for the better. Diabetes apparently sometimes takes its origin in shock, but the mischief once done is not to be undone by finding that the cause of the shock was an imaginary one.

Secondary anemia sometimes seems very amenable to psychic influences, but probably rather in an indirect than a direct way.

Idiopathic anemia, on the other hand, furnishes about as conclusive an illustration of the uselessness of an apparently well-founded encouragement as could well be.

What could apparently be more calculated to promote a cure, if a rational conviction of its possibility and actual presence could do such a thing, than the improvement in strength, in color, in well being, all sustained by the careful examinations of the physician who finds by his blood-count increasing amounts of red blood and disappearing abnormal forms; all but one of which the patient need know neither the presence nor the significance. And yet how fallacious! If well-grounded and reasonable expectations, seemingly almost realized, cannot cure, why should unreasoning and ignorant hope do so?

It was a remark of the older clinicians, that the mental condition of patients with disease above the diaphragm is much more cheerful

than that with disease in the abdominal viscera. If this disposition had a saving virtue, then pulmonary tuberculosis and valvular disease of the heart ought to be much more susceptible of cure than acidity of the stomach or constipation.

The value, importance and efficacy, as an adjuvant, of psychic influence in such cases is not to be denied, and no one would be inclined to minify it either in theory or practice, but it is most certainly not a direct one. It acts by encouraging the patient to persevere in such more positive measures as may be necessary in the particular case. It has been wisely remarked that it is possible for a patient to be too much encouraged, so that he is not willing and anxious, as he ought to be, to take the measures which are of the utmost importance for his recovery. The precise proportion in which hope and fear may be most advantageously combined is a matter for consideration in each case for itself.

No alienist would consider the "*delire des grandeurs*" of the paretic, in which he is convinced not only of his own abounding strength and universal powers, but of his perfect health, as a favorable element in the prognosis.

It is not probable that the most persuasive teaching of any sect can for the average man and for the moment produce a greater sense of well-being or lift him, in his own estimation, to a higher plane of thought than the administration of certain narcotics. The song may say,

> "Fill the bumper fair;
> Every drop we sprinkle
> O'er the brow of care
> Smooths away a wrinkle,"

but the pathologist will be likely to suspect that the "smoothing" process may not be altogether unconnected with edema, and finds that the more frequently this psychic influence is invoked the less of a prophylactic does it become to cirrhosis of the liver and arterial and other degenerations.

I think we are justified in saying, that over infections, degenerations, slow organic processes not dependent in any way upon mental activity, such as are those very largely which control the duration of life, the general health and the vigor of the constitution, direct psychic influences are practically *nil*.

Psychic influences come in contact with organic processes to affect them through the nervous system, and in particular through the vasomotor and secretory nerves, and symptomatically not only these, but also the ordinary motor and sensitive.

The secretions are, as is a matter of common observation, largely under the influence of mental impressions and of sensation. The activity of digestion is promoted by the pleasing taste of the food, and even its anticipation, and by the congenial company at the meal, and the reverse of this is also true. Solomon said: "Better is a dinner of herbs where love is, than a stalled ox and hatred therewith."

It has undoubtedly happened to many of you to be consulted by some patient who informs you that everything he eats hurts him, except when he goes out to a big dinner. It is even possible that a few hours from now may witness on a large scale, speaking with all due respect to the committee having the banquet in charge, a similar triumph of mind over matter.

Constant attention to the processes of digestion is well known to have a disastrous effect upon its comfortable accomplishment. The weighing of food and, worse yet, the constant use of the stomach tube by the patient, are practices much to be deprecated.

The effect of mental influence upon the movements of the bowels is notorious, and it is utilized not only in the every-day practice of the physician, but in the mystic séances of the faith curist. The effect also upon the secretions of the kidneys and skin is well known, and although this is usually pathological there is no reason why it might not under some circumstances be really, as well as apparently, curative. One form of diabetes insipidus is distinctly hysterical and might very easily contribute to the triumphs of some healer if he had the good luck to succeed a physician who had made an erroneous diagnosis of dilatation of the lower urinary passages, or even of interstitial nephritis, or if he were shrewd enough to suggest such a diagnosis himself, a diagnosis whose correctness might be made very conclusive to a nervous patient.

The intimate relations between the genital functions and mental and moral conditions need only to be mentioned.

Mental influences upon many cardiac phenomena of a functional character, including attacks of palpitation, are well known.

One of the speakers yesterday spoke of his experience in examining applicants for admission to the police force where a systolic murmur present in a great many cases disappeared when the successful issue was announced. Another reported that the sight of the dinner has had more effect on the blood tension as measured by instruments of precision than did strychnia.

Albumin has been found in a great many cases of students awaiting examination.

Suppose for the sake of illustration (although the hypothesis is so wildly improbable that it is difficult to entertain it), that our colleague had been a careless or an unscrupulous diagnostician and the systolic murmur had been announced to the friends of the patients as "heart disease" and then they had been told that instead of being admitted among the elect of this city they were going to be admitted to the Kingdom of Heaven on earth. He would have gained as great a reputation among the laity for his cures of "heart disease" as he has since among his professional brethren for his skilful and courageous use of antitoxin.

We have left, as a field for psychic therapeutics, those diseases or, more correctly, those sets of symptoms, which are closely connected with mental and emotional activity through the

consciously or subconsciously active, sensitive and motor nervous system, *i. e.*, diseases which we usually call functional, which do not always involve directly the nutrition or the processes of organic life but which may easily and frequently do so indirectly, and which interfere greatly with comfort, usefulness and the normal relations of the individual to his surroundings. But even here, where we should expect, and in fact do find, the greatest and most picturesque, almost the only triumphs of psychic therapeutics, there are many and great disappointing limitations. In many forms of insanity, which are apparently most especially appropriate for such treatment, we get nothing more than a relief, perhaps great, perhaps trivial, of some symptoms which are accidentally added to the fundamental processes of the disease. But this is an apparent and not a real exception, for there is little doubt that these are dependent upon organic processes frequently of a degenerative character.

But in melancholia, or, in more modern nomenclature, the depressed phase of the manic-depressive type, it would certainly seem that if psychic therapeutics had any field of action it could call its own it would be this. Of course no one can say how many mild or incipient cases of depression which do not come within the ken of the physician may have been cut short by a diversion of some sort — a bit of travel, the encouragement of friends, a chance remark, the influence of a faith healer or a piece of good advice from a physician, or by attention to the bodily functions, especially the digestion; but it certainly comes within the observation of us all how often the encouragement is utterly futile, how the patient while freely admitting the purely subjective origin of his troubles nevertheless confesses that he is absolutely unable to look at his surroundings in a reasonable and logical way, or rather perhaps that this admittedly true way has no effect upon his depressive emotions, and we are unable by argument or exhortation to present matters to him in any such aspect as to produce the desired change of feeling. We are as inexorably obliged to await the slower processes of nature as if we were dealing with typhoid or tuberculosis.

It is seldom that the faith curist even claims to cut short such a case, but he does not for that confess a failure, for he can always represent that the patient does not give himself up to the healing influence. This is perfectly true, but it is because he cannot, and this very ability which faith or religion or magic ought to supply it is conspicuously unable to do.

If the patient could do this he would have no need of a cure, and yet here, where it seems as if a change of emotional attitude would be so easy and so naturally obtainable by purely psychic means, is the very point where it has so slight an effect.

It is hardly necessary to reiterate the admission of the great value of psychic treatment, diversion, amusements, and best of all when possible an employment in which the patient can be interested, as adjuvants and for the relief of symptoms. The point is simply this, that the psychic end of the circuit cannot be controlled powerfully enough to set the emotional current flowing in the proper direction.

After such limitations as these we find left but little except cases in which symptoms, constituting in themselves a psychic disorder, counterfeit more or less closely something of a more serious and organic character.

The different varieties under which such disorders may show themselves would require, and have indeed occupied, volumes for their description. Explanations are not satisfactory and amount to but little more than saying in one way or another that there are inhibitory influences of purely mental or psychical origin which can interrupt or confuse or disarrange the normal associations of movement and sensation, just as effectually for the time being as certain organic lesions, but they are naturally much more amenable to other psychic influences and hence to treatment of the same kind.

Accepting the usual nomenclature, and having made the exception of more clearly classified groups, we find that neurasthenia proper is not especially amenable in its essentials to psychic influences except temporarily and apparently. Their value as adjuvants, however, can hardly be over-estimated.

If there is a real deficiency of nervous force, and not a mere counterfeit of it by indolence or timidity, it can hardly be expected that it will be at once restored by any simple brief stimulation of one part of the circuit. Time is required to bring back what has been overexpended, but other conditions being favorable, the psychic stimulation is necessary to enable the elements to profit by the nutriment brought to the cell, just as the muscles, after being kept at rest, for the sake of a fractured bone or the injury of their motor centre, need exercise to bring them back to their normal force. Hysteria, that ill-defined and perplexing psychosis which has been the foundation of so much that is false and illusory in therapeutics, is undoubtedly the peculiar and favorite stamping ground of the faith curist and miracle monger; not under its own name but under those of the organic diseases which it counterfeits.

A graphic clinical picture, showing with great scientific accuracy what can and what cannot be expected and obtained from profound psychic impressions, is to be found in Zola's novel of "Lourdes," powerfully realistic though not real, depicting the sufferings, the disappointments, the commercialism, the faith uplifted and the faith destroyed and the rare miracle cures of visitors to that famous grotto.

What are the methods of psychic treatment? Is there anything special or mysterious about them? Is it necessary for the self-respecting practitioner to put on the manners of the quack or to claim that he has in his control supernatural agencies, or that he should advise his patient to give himself to the study of empty verbiage and

theories which have no meaning to the healthy mind?

I do not think these questions can be answered in every case alike. Two diagnoses are necessary — that of the disorder and that of the patient. It has been said recently by distinguished members of our profession, and by other eminent citizens, that the utmost honesty and frankness may be used in dealing with patients and that they may be told the exact truth. Both may have been correct from their point of view, but most practitioners have to deal largely with persons who are not soldiers or philosophers or saints, who are not tired of life, and above all, do not like to be told of their own weaknesses. I think the practitioner is justified in giving the patient the benefit of the doubt, when there is any, and in putting the best side of the case before him, without insisting on the other. The average man will not be comforted by being told the exact percentage of recoveries in the disease which bears the name of what he thinks he has. He needs a unanimous vote of confidence. One reason why a man with a perfectly sane and healthy mind wishes to consult a physician is that he may throw upon his shoulders the responsibility and free his own mind from all the ifs and buts which weigh heavily upon it and retard his recovery.

Even the lawyers admit that there are many cases where both sides have a certain amount of right, and that it is more important that the case should be *decided* on one side or the other than that it should be left indefinitely *undecided*, because absolute justice cannot be done to both sides.

When the physician is sure that he is dealing with a case of neuromimesis he cannot be too strong in his encouragement and exhortation, and he may then assume more of authority than comes from a simple scientific knowledge, which would very possibly be scouted by the patient. He had better fall back on his prestige and reputation and such measure of oracular mien and expression as nature may have endowed him with, and give no reasons, and, above all, not give the true name of the disease. This is an average, and not a universal, rule. There are patients who can bear to be told the truth — and nervous ones at that — but it is well to study the patient's disposition as well as his disease before you are too frank in your expressions.

But when nature kindly draws a vail before the dangers of the future, I think we have no right, for the sake of absolute scientific accuracy, to draw it aside and destroy the hope which may be the last fighting chance.

There are various ways in which treatment addressed to the patient's mind may be given, ways as different as there are patients and physicians. One practitioner cheers his patient by judicious pleasantry, another by a carefully reasoned exposition of the grounds upon which his recovery is to be confidently looked for, another by religious influence; one by hypnotism, another by non-hypnotic suggestion; one quack by the confident repetition of an absolutely unsupported and probably absurb assertion, another by absolute silence.

The methods may be various, but the essential thing is the implanting not merely in the patient's reasoning and conscious mind, but in what we call, as it seems to me somewhat inconsistently, the "sublimial consciousness"; that is, the store room of past and forgotten associations, ideas and emotions of which the patient is not at the time definitely aware, but which may be in various methods reached, the idea of recovery and health, of the unreality of the pains, of the ability to walk or to talk.

Our late associate, Dr. Russell Sturgis, used to practice a method which he considered of great value in utilizing the slighter degrees of hypnosis for diagnosis and treatment. It seemed to me that it went but little beyond inducing a specially confidential and persuadable frame of mind and completeness of recollection, so that the causes of abnormal psychical conditions became more clearly revealed and consequently more thoroughly removable.

Breuer and Freud have used a method which does not necessarily depend upon hypnotism, but upon successive séances of inquiry and upturning of the subliminal consciousness to its lowest depths.

According to their theories, hysteria is always based upon some special psychical injury at an early age, its concealment and the suppression of the appropriate motor reaction; as, for instance, in the case of an official who did not dare to resent the insult offered him by his superior, but became nervous and hysterical until he had confessed the whole matter fully and got well.

The great remedial value of a full and free confession, often perhaps of some trivial affair, is well recognized in our profession, although less formally than by the Catholic church and some others.

It is not uncommon in hearing patients relate their wonder cures, or perhaps more frequently after the stories have passed through more than one narrator, to learn that they had no faith whatever, but submitted to the treatment in order to please importunate friends, and so on.

I venture to doubt the correctness of this. I have no doubt that often when patients may be as willing as any of us to admit the foolishness of the methods pursued, they have yet a real but subconscious belief that something is to happen. In some cases the belief in something weird, uncanny, seems to be an essential point.

At to the particular doctrine taught in the various sects there is little choice, except that it should not be too repugnant to the patient's deep-seated convictions, religious or social.

A strenuous repetition of a positive assertion seems an absurd sort of method to be advanced when unsupported by any argument, proof or illustration; but if any one doubts its efficacy among a proportion of mankind large enough to have a great commercial importance, I would ask him why medicine makers find it to their great

pecuniary advantage to disfigure miles of railroad and square miles of territory with simple repetitions of the statement that "Blank's Pills cure everything," or that "Children cry for Catcher's Gambogia."

Many of the various modern mechanical means of treatment, especially those which are used in chronic nervous diseases, owe a certain part of their efficacy to the constant impression of something being done, of taking up the patient's attention while nature and time are taking their slow course. A prescription of this kind may be considered as having, like many prescriptions of drugs, a proportion of mental influence as one of its ingredients.

Electricity, for instance, is difficult to disentangle from this element of error. I recollect on one occasion in a society of neurological specialists an apostle of a peculiar form of electricity was exhibiting a new electrode, and on being rather hard pushed by the other members, not only as to the advantages of that particular form, but of electricity in general, fell back from one line of defence to another until he reached the last resort of saying that it had a very good moral effect in hysteria, which is no more than might be said of any drug in or out of the pharmacopeia, from abelmoschus to zygadenus, if administered with due solemnity, or of no drug at all.

The various kinds of active exercise have the very distinct advantage that the patient is kept from thinking of himself not only by the unusual sensations, but by being obliged to use his will in a definite direction, which is exactly what he needs to do. This is especially to be seen if the exercise consist in some employment in which he takes a real interest, and this must, of course, vary greatly with each individual patient.

The beneficial effects of certain systematic exercises in scleroses of the cord is not to be accounted for entirely on this ground. As I presume will be more fully and scientifically set forth by my successor, it is a question of readjustment, and not of restoration. The damaged tissue cannot be replaced, but other comparatively sound cells, nerves and muscles may be able, under training, to take up a part of their work and carry on the function with greater or less approach to perfection.

In how large a proportion of the ordinary work of the practitioner, beyond the cheering and encouragement that he may always offer to some extent as a contribution to his patient's comfort and happiness, is psychical treatment of consequence? According to some sects, the whole of medicine, surgery and obstetrics, although it is understood that recently in the highest circles in the latter departments the true believer is graciously permitted to seek human in addition to divine assistance and receive relief through agencies which do not act merely through the mind. According to the skeptics, only the cases of nervous and silly women.

How are we to account for the hundreds of assertions of cures obtained by all sorts of means which range from the crudest mixtures of common, perhaps inert, drugs, to the most transcendental imaginings of cultivated and intelligent persons?

If there were time, there would be an opportunity for a digression on the meaning to be attached to the words "cultivation," and "intelligence." But we may leave this aside and allow for a very liberal discount for the lie pure and simple, paid for by the advertiser to the patient perhaps, and heavily and appropriately to the journals which are willing to take such money with the same hand that does not refuse even the criminal advertisement. Then come other lies in various grades.

It would not be difficult to show by example that a person may be highly cultivated, intelligent, even with scientific talents of a high order, and yet under the influence of feelings and desires entirely uncritical and credulous.

We should then find a very considerable percentage due to imaginative but entirely honest exaggeration, by the shutting of the eyes to one set of facts and the opening them very wide to another. If time permitted I should like to describe one instance which happened to display both sides to me, which shows how the mind seeking for a miracle manages to get itself gratified.

Darwin makes the very pertinent remark that he found that facts which were in disagreement with his theories slipped from his mind much more easily than those which harmonized. If such a cause of error required to be guarded against by a Darwin what can be expected of ordinary humanity, which is not only not on its guard against it but cherishes it with fond affection?

Then there is the small residuum of genuine cases in which some form of functional nervous disease, a paralysis, a contracture, a neuralgia, a convulsion, which has undergone all sorts of scientific treatment in vain, yields in the hands of a faith curist.

Statistics in such matters are obviously very untrustworthy. A few years ago Mr. H. H. Goddard prepared for his graduation thesis at Clark University a paper upon this class of cures, and was kind enough to show me some of the answers returned to him, some of them referring to patients who had been under my care. He came in contact with one man who had had a good deal of success in dealing with many cases of which a considerable proportion were evidently functional nervous, and who was willing to give information which Mr. Goddard believed to be full and candid. He was not a medical man and his diagnoses were consequently not very trustworthy but were probably honest. He was willing to speak frankly of the cases which were not cured. This information Mr. Goddard compared with the published statistics of the celebrated medical hypnotists as representing the scientific side of the question. He found that in a general way the two sets of cases corresponded fairly well both as to percentages of cures and as to the class of cases benefited.

"He (Dowie) says, in a certain issue of his paper: 'I pray and lay hands on 70,000 people in a year.' At that rate he would have prayed with 175,000 in two and one-half years. But in the two and one-half years immediately preceding this statement, he reports only 700 cures. The conclusion is indisputable that only a small portion of those prayed with are cured." — Goddard.

As regards the every-day practice of medicine with its very great proportion, among the acute cases, of infections; and among the chronic infections and degenerations, scleroses and new growths, psychic therapeutics as a primary and essential treatment finds but little scope, while as an adjuvant to the healing forces of nature and time it is and always will be a most precious resource of the physician, and he who wields it most judiciously will be the most successful.

Among the psychoses, notwithstanding there are many and great limitations even upon the side which we must still consider functional — though any day some new method may show us the incorrectness of this view — the relation is reversed, and the physician must look upon the building-up processes and the various appliances in use, pharmaceutical and otherwise, not only for their real and direct but for their mental impression.

For either case he must look before all for a diagnosis.

A CONSIDERATION OF MENTAL THERAPEUTICS AS EMPLOYED BY SPECIAL STUDENTS OF THE SUBJECT.*

BY JAMES J. PUTNAM, M.D., BOSTON.

THERE are but few kinds of disorders which interfere more with the happiness of the community than those which cause a painful and hampered action of the mind though without implying the presence of serious mental derangement. The disorders to which I refer are mainly those characterized by insistent thoughts, emotions and impulses, "obsessions" and "morbid fears," which the patient recognizes as largely causeless yet cannot shake away. Starting, perhaps, with some severe or prolonged emotional strain, and on the basis of some weakness or defective organization which one would call hysterical or neurasthenic, these morbid tendencies become deepened by habit, and expand into complex systems or "temperaments," which mingle their influence with every motion of the mental life; or they show themselves in the form of occasional outbreaks which really have a definite, though hidden, history, or as constantly recurring and seemingly causeless tricks of muscular movement, the "tics" of the French writers, and in many kindred ways.

Even the "fatigues" and faintheartedness of neurasthenia are, in some measure, to be classified amongst these inco-ordinations of the mind.

These affections cloud the happiness of many persons whom every doctor meets upon his daily rounds, and yet, in spite of this fact, they are far more susceptible of relief, under prolonged and skilful treatment, than is commonly supposed.

On these accounts there is no branch of therapeutics more deserving of study than that which forms the subject of this conference. Of course, the mental therapeutics may rarely be the only kind of treatment to be thought of. Sometimes an impaired general nutrition stands in the way of improvement, or some local ailment, which perhaps a gynecologist or an orthopedic surgeon can remove, has lowered the vital tone just enough to make the patient a prey to troubles which would otherwise have been resisted, and if such a physician or surgeon is wise he may make his treatment the starting point of a new departure of hopefulness to which, perhaps, no other avenue could have been found.

But after the ground has been cleared through a consideration of these possibilities, there remain innumerable cases where some sort of specialized mental influence or education has to be employed. Of course, in practice, each case has to be studied by itself, but it will be useful for the purposes of this paper to distinguish between the patients who are more or less continuously and painfully conscious of nervous weakness or hypochondriacal depression and those whose symptoms present themselves intermittently, or only under certain conditions. The patients of the former class are mainly those suffering from neurasthenia, with its attendant distress of body and mind, while the sceond class is represented by the sufferers from morbid fears of specific sorts, or occasional outbreaks, often of a serious nature, which may, for convenience' sake, be classed as hysterical. In the case of the first of these two classes the question of bodily nutrition and reflex excitations is much more important than in that of the second class, and when these questions have been eliminated the problem as regards the mental state is the relatively familiar one of seeking to secure the conditions under which the patients can live a relatively active and useful life, of inducing in them, in an adequate form, the sentiments of courage, confidence, patience and determination, and making them familiar with the dangers that are likely to threaten from without and from within.

It frequently happens that the question of happiness or unhappiness of patients with severe forms of neurasthenia depends largely on influences which would ordinarily be classed as social rather than medical, though, in fact, the physician can help greatly in determining what the outcome of these influences shall be.

I have heard so many patients say that they had formerly entertained great disdain for nervous weakness, if not for the patients who allowed themselves to be controlled by them, that I think such sentiments must be very common in the community, and must be the cause of many needless burdens of distress. The time must surely come when nervousness and even serious

* Read at the Annual Meeting of The Massachusetts Medical Society, June 8, 1904.

mental derangements will be regarded in much the same light as other forms of illness, and with the growth of such a sentiment as this there will be great mitigation of individual suffering. For, to a great extent, a man's estimation of his own misfortunes is a reflection of the estimate made, or which he thinks is made, by others. I am inclined to believe that the real root of the disdain to which I have referred is sometimes a sense of dread for themselves, on the part of those who entertain it, which they try to suppress by an instinctive affectation of superiority.

It is quite natural that where influences of a spiritual order are in question, laymen should feel themselves on a par with the physician, and the fact that they often do so has shown itself in a thousand ways.

Most of the therapeutic influences coming under this head have taken their coloring from philosophy or religion,[1] and the patients in whose behalf these influences have successfully been exerted have often gained, through their illnesses, an insight into a higher life. Within the past decade another interesting and successful enterprise has been set on foot by a citizen of Zurich, Grohmann by name and originally an engineer by profession, consisting in a species of sanitarium where the healing influences are represented by real work, and simple habits of living, in a small community. The founder of this almost unique establishment is a man of intelligence, devotion and force, and his work is carried on under the auspices of some of the best physicians of Switzerland and Germany. The superintendents of sanitariums might well learn a lesson from this hardy effort, which is characterized, perhaps, not so much by novelty of idea as by novelty in the thoroughness of its execution.

It was intimated above that neurasthenia sometimes shows itself under a form that might be called "hysterical," but to avoid a term which is susceptible of misinterpretation, one might say it sometimes happens that persons who have suffered from neurasthenia fall into habits of invalidism which cling to them after they have really recovered from their original illness, and which the memory of their former sufferings makes them dread to disregard. The "neurasthenia" of youthful adolescence is often of a similar order. These are cases which might, strictly speaking, be better considered with the disorders of the *second class*, of which we are about to speak, but in fact it need only be said of them that they offer an excellent chance for intelligent and vigorous handling, the aim of which is to restore the confidence which has been lost.

The *second class* of cases, represented by the morbid fears, fright psychoses, insistent ideas and epileptiform or hysterical outbreaks, are much harder to deal with, and yet it is with regard to these that some of the best work of the last ten or twenty years has been done.

[1] A suggestive and stimulating essay entitled "The Spiritual Treatment of Neurasthenia," by Arthur A. Cary, is published in The New-Church Review, for April, 1904.

Fortunately, it is also true that some of the insistent fears which seem so invincible when they are present turn out to be possessed of little substance if resisted boldly and not taken too seriously. Under these circumstances a strong effort, or a series of graduated efforts, in which the patient is firmly supported by the physician, may overcome a morbid fear of long standing. The determined adoption of the attitude of dogged indifference, based on confident and authoritative advice, will often suffice to carry the patient through the first severe trials. Sometimes the triviality of a distressing but causeless fright can be made to appear more evident through the demonstration that it can be relieved by a trivial distraction, just as a slight turning aside of the attention may relieve the cramped mental attention of a balking horse.

On the other hand, there is an equal or greater number of insistent ideas, which seem trivial yet are so hard to master, that one is reminded of the legend of Thor, who in vain tried to drain off the horn of wine that had been given him, and found, at last, that it was connected with the sea.

It is a noteworthy fact that a good share of the advance in modern psychology, involving the so-called psychology of the sub-conscious life, is based on data which are the contribution of medical science. These studies have been of immense value in the interpretation of those forms of mental inco-ordination to which allusion has been made. They have taught that while we regard ourselves as free agents and our mental life as forming one harmonious mechanism, no one is really as free, no one's life is so complete a unity, as he would like to think.

Every one of a man's acts expresses, in a sense, a history of his life. What he has done before he will tend to do again, and the old habits and motives (themselves the expression of his total and partly unconscious experience) will ever strive to reassert themselves.

This principle will be admitted, but it is not usually realized how strongly and instinctively a man lends himself to self-deception in this matter, not what an important bearing this self-deception has in causation of disease. It is on this point that I now wish particularly to speak.

Under the exigencies of competing successfully with our fellow-men, a strong instinct has developed itself which leads us to push to the front, into the field of our habitual consciousness, only those memories and motives which seem of distinct utility in the attainment of our present, conscious needs. This arbitrary group of memories we call "ourselves" and we push out of sight those experiences of our past life which do not harmonize therewith.

It is of no apparent use to a man to recall a painful emotion or a serious fright. If he could he would gladly wipe them out from the records of his life, and, as it is, he strives to thrust them into the background, not realizing that he might, if he had the power, training and insight, con-

sciously assimilate these experiences, and that his present motives would be fuller and richer for their presence..

But it often happens that these painful experiences and memories which, in his ignorance, he thinks so needful to be rid of, often refuse to be banished thus cavalierly. His refusal to deal with them does not make them disappear from his mind, but as he cannot or will not assimilate them and utilize them and acknowledge the lessons which they could have taught, they lead a sort of parasitic existence in the mind and form a species of organization hostile to his well-being. And thus it happens that a serious breach is made in the unity of the conscious life, and a breach that may constantly tend to widen.

To this process the term "dissociation of consciousness" is often given, and it is one of far-reaching significance. Thereafter, when a call for action comes, a double set of reflexes — as for convenience we may call them — will tend to show themselves; one set expressive of the organized experiences, memories, and motives which the individual would be glad to have reckoned as constituting his personal identity, the other set expressive of the mental experiences which have clustered around some of these unassimilated painful emotions as a center.

Thenceforward, also, the conscious mental life will be marked with confusion, with a sense of an unexplained something which is wrong, and with inefficiency and self-distrust. In many cases the disorganization has its roots even far back in the years of childhood.

The function of the doctor is to heal this breach, to neutralize the dissociation which has taken place, and to restore the previous unity of the mind.

It is with regard to these cases that the method first employed by Janet, and by Breuer and Freud is of such great importance, and although the first communications of these writers were made a good many years ago, it is to be observed that their painstaking labors and those of a few others who have worked upon the same lines, amongst whom are to be mentioned our own colleagues, Russell Sturgis, Hamilton Osgood, Morton Prince, and Boris Sidis, have strongly reinforced the value of the facts as first stated.

It has been found that painful experiences are often enabled to work mischief just because they are hidden from the patient's view. The aim then ought to be to bring back the hidden experience into the clear light of consciousness, so that its real significance can be estimated, after which the reorganization of the disordered forces of the mind is likely to take place of itself. Sometimes the result thus aimed at can be attained by inducing the patient to talk at length and in full detail about all the circumstances connected with the onset of his illness. So strong, however, is this instinct for thrusting the unwelcome experiences out of sight, that the patient may, at first, declare himself wholly unable to recall any facts of which the physician can make use for making clear to his own mind the exact history of what has taken place. Nevertheless, if the patient co-operates voluntarily by withdrawing his attention from all distracting thoughts, relaxing body and mind, allowing his memory to be led by skilful questioning, and forcing himself to narrate every detail, however trivial or painful, connected with the onset of his troubles, it may be found at last that the whole story will be disclosed which the patient had instinctively excluded from his memory, and that, in this way, the chain of morbid links, stretching from the patient's present condition back to the experiences in which his symptoms had their rise, can be laid bare.

In a certain sense, it may be said that the hands of the clock are thus turned back to the date of these events, and that the patient is made to live over again that period of his life. Under these circumstances one can deal with him as one would have been glad to deal with him at that time, but with the difference that he is now more in the mood of responding favorably to encouragement and to reassurance. It may thus be said that, in a new sense, it is possible to " minister to a mind diseased," to "pluck from the memory a hidden sorrow."

This method of analysis of the patient's memory is useful for the purpose of diagnosis as well as of treatment. Through it the discovery may be made that conditions which had been thought to indicate the existence of serious forms of epilepsy are really curable attacks of a hysteroid character. Sometimes this analysis and treatment can be carried out more effectively when the patient is placed fully in the hypnotic trance. When this is decided on, the object of the treatment is explained beforehand, and the patient is assured that when he wakens from his trance he will remember clearly all the facts connected with the painful experience which it has been sought to discover and to remove.

The thought of hypnotism brings unpleasant associations to the minds of many persons. It has been thought that it tends to loss of independence and weakening of the will, and that it is, altogether, a practice to be discountenanced. As a matter of fact, these dangers do not, practically, exist. Even at an earlier time, when hypnotism had its day as a popular craze, the evils that were attributed to its use were not due to the hypnotism as such, but to the conditions of morbid excitement that went with it. Certainly, when it is employed by skilled persons, for the purposes that I have suggested, and with the sole desire of accomplishing through its means the object of the treatment, which is to make the patient master himself, there is no objection to its employment, and it may be used as a means of strengthening, and not weakening, the will, with the same confidence that this result is sought as the outcome of a rational conversation.

It is an idle criticism to say that hypnotism should not be employed because it induces states which are "morbid" or analogous to hysteria. We are continually inducing " morbid " states for therapeutic purposes, as by ether and mor-

phine, and artificially limiting and rearranging for special ends the movements of our conscious life. In each case, the only question is as to the value and significance of the ultimate result, regarded in all its aspects.

The cases of "traumatic hysteria," which occur so often in every physician's practice, afford remarkably good illustrations of some of the points which have been mentioned in the foregoing remarks. Thus, we have in them examples of typically painful and insistent experiences, which are here of especial interest because they often occur among persons not previously of an hysterical temperament. The instinctive effort to push the memory of such experiences out of sight, and likewise the fact that they really continue to live and to act with gathering force, are clearly brought out in the histories of these patients. Frequently such a person will say that he has followed his usual avocations, and that the thought of his mishap has not been prominently present to his mind, and even that he cannot recall distinctly the events that occurred. Nevertheless, a careful investigation will show that in his dreams at night, or in hysterical outbreaks, the circumstances of the accident are reproduced in minute detail. It also may appear that one arm or leg or one half of the body feels weak and is lacking in sensibility, and that effort of every kind is attended with fatigue and distress. Such a patient does not know that he has been suffering from a dissociation of his consciousness, and that while he has been instinctively striving, for his own peace of mind and for the sake of conventional appearances, to present the same front to the world that he presented before the accident, he is really under two masters, who do not act in harmony; that his mental forces are like an army through whose ranks a more or less organized demoralization has been spreading. He is not aware that the anesthesia may, for the dissociated portion of his consciousness, be a hyperesthesia, nor that the weakness and fatigue indicate that he is carrying a burden that is unseen.

Sometimes the patients of this class get well readily of themselves, under the influence of a return to their usual pursuits, but, in my experience, this result is less common than that of a more or less prolonged invalidism, unless, indeed, the case is taken in hand early and the patient is intelligent enough to put himself under favorable conditions for a cure. We have recently been able to relieve, at the Massachusetts General Hospital, one such patient who was suffering in an acute form from the anesthesia and hysterical tremor consequent on an accident, and in spite of the fact that a suit-at-law was pending.

The foregoing brief and diagrammatic sketch of certain aspects of mental therapeutics must be supplemented by at least a reference to certain other points.

It should be distinctly remembered that the necessity for mental treatment, even in the severer cases, does not exclude the necessity for general and local treatment, and this is true even for those conditions where, by strongly turning the mind in one or another direction, and enriching the conscious interests, we can enable the patient to overlook and forget his sufferings. We may, indeed, sometimes accomplish this result, for a time, by exciting a sort of mental exaltation, but then the mental treatment becomes a species of narcotic, and though narcotics have a distinct place in rational medicine, their employment is liable to great abuse and needs to be safe-guarded with especial care. The fact that the small boy's toothache disappears when he arrives at the dentist's door does not prove him to be beyond the need of the dentist's attention.

On the other hand, the local or general treatment, in the hands of a physician who really understands the mental needs of his patient and is prepared to use his influence in the best way, is often productive of a degree of benefit which the neurologist alone cannot secure.

The contrast between the expert mental therapeutics of the present day and that of an earlier period lies, thus, largely in the clearer definition of the objects to be sought and the steps by which these objects are to be attained. Most of the newer leaders of thought in such matters have turned aside from the inquiry, What effects can be induced by mental influences, to the study of the diseases for which these influences, among others, are of use. It will be remembered, for example, that, some fifteen years ago, a wave of revived interest in hypnotism spread over this community. Liébault and Bernheim had recently published their marvellous tales, the controversy between the schools of Nancy and of Charcot was still fresh, and a few of our townsmen had returned from abroad to show that Americans too could be hypnotized and cured of many ills. For a time the word hypnotism was on all lips, and the list of its accomplishments grew longer day by day. Many books were published, and a number of men, some of them of great ability, devoted themselves exclusively to that branch of practice. Their experience has certainly been of the greatest value, and many of the same men are still working and publishing on the old lines. On the whole, however, there has been, I think, a clearer recognition of the fact that one cannot deal satisfactorily with "suggestion" until a great deal more has been learned of the nature of the diseases in the treatment of which "suggestion" sometimes proves a partial aid, and of late years the pathogenesis of "insistent ideas," of "multiple personalities," of hysteria, and of the hysteroid forms of epilepsy and neurasthenia, has been studied as never before.

These studies have taken the form of clinical researches of the most minute and searching kind. Through analytic case-histories, patiently recorded, it has been sought to picture the mental history of sufferers from such disorders as those enumerated, with the same sort of fidelity as is displayed in the descriptions of the anatomists.

These researches have already placed mental therapeutics upon a far more rational footing,

and as time goes on their effects are sure to be more and more apparent.

The neurologist of the future will seek to treat his patients upon the basis of a broader and more intelligent study of their individual experiences and of the influences to which they have, severally, been exposed. He will try to leave each one better able to understand himself, less inclined to waste his strength in aimless self-reproaching, or to yield to paralyzing fears, and more inclined to engage hopefully and with interest in the task of successfully asserting his intelligence, his conscience and his will. And these results will not have been attained, or at any rate it will not be sought to attain them, by appeals to superstition or ignorance, but by methods which reflect the true spirit of scientific research.

No attempt need be made to draw a sharply dividing line between physical and mental therapeutic agents. It is desirable, on clinical grounds, to recognize that a kinship exists between the influence that improves the nutrition of the brain by increasing the harmony and efficiency of its functions, and that which reaches the same end by improving the quality of its nutrient fluids, or the mode of their distribution. With this principle borne in mind, the physician will be more apt to treat his patients from various points of view simultaneously, and not to neglect one for the other.

It seems impossible, in this brief communication, to refer by name to the men who have placed this branch of medical science on its present footing, or to refer to the attempts in the way of treatment with which I have become personally familiar. I must, however, in justice mention that the work of a number of our colleagues in Boston has contributed materially to the building up of this new branch of medicine, and has justified the placing of their names alongside of those which are so familiar to all students of the foreign literature with relation to this topic. Nor can I forget that it is owing mainly to the devotion and the skill of my friend and associate, Dr. George A. Waterman, that the winter's work at the Massachusetts General Hospital, in the Out-Patient Department and in the neurological ward, has been fruitful during this past season as never before.

OPERATIONS ON THE STOMACH, WITH REPORT OF CASES.

BY JOHN C. MUNRO, M.D., BOSTON.
From the Surgical Clinic, Carney Hospital, Boston, Mass.

(Continued from No. 6, p. 152.)

No. XCVI. Male, sixty-two years old, referred by Dr. Boland.

For three years the patient had had pain in the stomach, and for two years he had been unable to work. The pain would come two to three hours after eating, and during the night it was so severe that he could not sleep. He had had some vomiting, of excessive amounts and of retained food but without blood or coffee grounds. There was much eructation of gas with relief. Marked constipation for two years. He had lost about thirty pounds in two years and had been under treatment at the various hospitals, etc., without relief.

At operation, at the Carney Hospital in June, 1904, a dilated sagging stomach was found with a hard scirrhous growth at the pylorus adherent to the gall bladder near the cystic duct and to the liver which was directly infiltrated. The patient was in no condition for radical operation, so a posterior gastro-enterostomy with clamps and sutures was made and the abdomen closed. There were no enlarged lymph nodes to be felt, but there was malignant infiltration into the liver.

Convalescence was most satisfactory, and he was discharged shortly afterwards eating and digesting well.

Of the foregoing thirty-two patients operated upon for malignant disease not a single case came early enough for radical cure. For the early deaths after operation less blame must be attached to the interference than to the long delay before operation was allowed. A few cases were of the fulminating type, and early operation, if it had been obtained, would have been futile.

In many of the histories of the malignant cases in the hospital records, the early symptoms were not put down and probably were not inquired into. In all probability careful cross-examinations would have brought out suggestive and pertinent data by which malignancy could have been suspected.

Practically no case, however hopeless, was refused operation, and the few that were so markedly benefited give encouragement in dealing with these forlorn people.

In several, the degeneration of a benign ulcer was most probable, and it emphasizes the occasional danger in treating a chronic ulcer as though it would remain benign indefinitely.

The rarity of vomiting as a symptom should be referred to over and over again, as demonstrated in these cases.

The combination of advanced age and steady loss of weight is very suggestive. Persistent pain in the stomach was common. In a few instances it was relieved temporarily by the ingestion of food.

Just as in chronic ulcer the steady limitation in diet is one of the most valuable clinical symptoms, especially if it takes place in spite of rational internal treatment.

Some patients were watched by their physicians until a tumor could be felt, in order to make a diagnosis, in the face of more leading signs as shown in emaciation, pain, vomiting or nausea, retention of food, etc.

However willing we may be to attribute death in the worst cases to the operation, yet to one who has watched them closely it is clear more and more that the prolonged starvation and the absorption of decomposed and never digested food play the most important role, although the end occasionally may be hastened a few days by operation.

The following seven cases of perforation are grouped together.

No. XXXVIII. Female, twenty-one years old. For three or four years she had complained more or less of constant pain and distress in the stomach. She had never had hematemesis and, in fact, said that she had never vomited till four days before entrance to the City Hospital, October, 1896. Pain in the stomach became more severe than usual at that time, but she continued at her work. This pain persisted, and the day before entrance, in the morning, suddenly became very severe. She vomited and had a chill. On going to bed the abdomen at once began to distend. The vomiting ceased shortly afterwards, but the epigastric pain and distention continued. At entrance she looked bleached, with a pinched, anxious face, a distended, tender abdomen, with the tenderness and rigidity most marked in the left side below the costal border. There was rapid, shallow respiration and quick pulse.

At operation the peritoneal cavity was found to contain gas and stomach contents. A round, punched-out perforation was found a little anterior to the lesser curvature, at the pyloric end of the stomach, barely admitting the tip of the finger. The surrounding wall of the stomach was too brittle to allow the ulcer to be closed by suture so the pyloric end was drawn forward to the surface of the parietal wound and sutured there into place. The general cavity was then flushed out with sterile water and drained with iodoform wicks and a glass tube. A rubber tube was sutured into the stomach through the ulcer and carried to the outside of the dressings. Although the patient was in bad condition at the beginning of operation she stood it fairly well, stimulation being given freely. She improved for four days and was apparently on the road to recovery, when, in the evening, she suddenly collapsed and died with much suffering.

Autopsy showed a large pocket of pus deep in the pelvis. The ulcer was well walled off from the general cavity. Had the pelvis been drained as has been emphasized by Lund, I think recovery would have taken place almost without question.

No. XXXIX. Female, twenty-one years old. Entered the City Hospital in October, 1897.

She had complained of dyspepsia for several years, at times vomiting, but without blood until five weeks ago, when she vomited material that looked like coffee grounds. Two weeks before entrance there was severe pain in the left side of the abdomen, lasting for twenty-four hours, which on the following day was very severe, but did not last long. This pain she described as of a gnawing character. For a long time she had complained of soreness over the gastric region. Four days before entrance the pain in the left side was more severe, coming on suddenly with vomiting, but without blood. Since then the pain had been continuous while the tenderness of the abdomen had been general from the start. The bowels, naturally constipated, had moved frequently. At entrance the abdomen was distended and exquisitely tender. She was transferred from the medical service on the day of entrance, for operation, when edema of the abdominal wall was found, especially marked above the umbilicus. The peritoneal cavity contained gas, pus and stomach contents. An opening into the stomach was found on the anterior wall near the lesser curvature, about the size of a lead pencil, with thickened, cheesy edges. This could be turned in and sutured. The general cavity was then flushed out and the region in the neighborhood of the ulcer was packed with glass tube and iodoform gauze. The abdomen was filled with salt solution, the foot of the bed was elevated, and stimulation used freely.

The following day she was much weaker, and two days after operation she died. No autopsy was obtained, but examination through the wound showed that there had not been any leakage, the wicks being clean and dry.

No. XL. Female, twenty-one years old, entered the City Hospital in December, 1900.

For six months or more she had had stomach trouble, with pain coming on immediately after eating, and relieved by vomiting. She had never vomited any blood nor passed any dark-colored stools.

Two days before entrance she was taken with sharp pain in the upper abdomen three hours after eating, followed by vomiting but without blood. During the evening the pain became severe and was followed by a chill. At entrance she felt better but was vomiting. She looked sick, with drawn face, moderate distention, tenderness and spasm all over the abdomen, most marked in the epigastrium.

Operation at once showed cloudy serum beneath the peritoneum and diffuse marked fat necrosis of the omentum. There was thin pus in the pelvis and epigastrium. The omentum was found surrounding a large pocket of bile and thin pus, either behind the omentum or in the lesser peritoneal cavity. In addition there was another large pocket of bile, pancreatic fluid and pus in the hepatic region. There was fibrin with necrotic areas in the pyloric end of the stomach, and on the anterior surface close to the upper border, was a clear, punched-out opening a quarter of an inch in diameter, which was easily closed with a double layer of mattress sutures. The cavity was irrigated thoroughly, both the epigastrium and pelvis being drained. Just as soon as the operation was started the patient went into collapse, and although operation was done as rapidly as possible she was in profound shock at the close. She rallied a little, but died in about twelve hours.

Partial autopsy showed the location of the ulcer as described above. In this case there was a pancreatitis in addition to the perforated ulcer.

No. XLI. Female, twenty-five years old, entered the Carney Hospital medical service in November, 1903. She had complained of indigestion all summer, with sharp pain in the epigastrium in the morning and soon after eating. There was some gas, and at times she vomited several times a day, followed by freedom from vomiting for a week. The amount had always been small and nausea preceded the vomiting. Nine days before entrance she complained of a sharp epigastric pain, radiating to the right side and left flank, back and shoulders. It was so severe that she fainted. The pain continued until the following night, when she was given castor oil, and vomited. She then went to bed for five days, at the end of which time the vomiting and pain returned. The day before entrance she vomited and was tender along the lower costal border. The abdomen was tense but not distended. There was marked tenderness in the left side, through the ribs to the loin, as well as in the epigastrium. She was transferred three days later to the surgical side, with severe pain, high leucocyte count, and marked restlessness.

At operation there was a large quantity of foul pus and gas in the abdominal cavity. The anterior wall of the stomach formed the floor of the abscess cavity, the pus burrowing over the dome of the liver laterally, on both sides, as well as beneath it. Below and laterally the dilated stomach was adherent to the anterior wall, evidently limiting the spread of the pus. No definite perforation was seen. The stomach was adherent to the liver and these adhesions were not disturbed except to open whatever pockets there were. A small opening was made over the pubes. But the lower portion of the abdominal cavity was found free

of infection and this wound was closed at once. The upper wound was packed with iodoform gauze and a glass drain, the patient being no worse at the end of the operation than at the beginning.

The purulent discharge continued for a number of days, while she slowly and steadily improved. At the end of six weeks she was discharged much relieved, to our Surgical Out-Patient Department, where she was treated for several weeks for a granulating wound in the upper part of the abdomen. In March, four months after operation, she was at work and in good condition. When seen in May she was still in good condition and working steadily.

No. XLII. Male, forty-five, was seen with Dr. Brown of Newburyport in October, 1903.

When twenty years of age he had attacks of abdominal pain somewhat similar to the present one, coming on every few months, but not so severe. He would be sore for a day or two, but gradually outgrew these attacks. For several years he had had indigestion, which disappeared entirely at times. Pain had always been in the epigastrium, coming on about an hour after eating. He had never vomited. For a few days before I saw him he had felt as though there were a lump in his epigastrium. The night before I saw him he was awakened with very severe epigastric pain. Dr. Brown saw him an hour later and found him in agony with a hard, rigid belly. He had vomited somewhat but without blood. He was given morphia in a large dose and taken at once to the Newburyport Hospital.

At examination, six hours later, he had abdominal spasm, most marked in the epigastrium and right hypochondrium.

Operation showed free gas, bile and mucus in the abdominal cavity and a small round opening in the anterior wall of the duodenum close to the pylorus, from which gas and fluid were escaping copiously. About the opening there was slight thickening and a faint scar that would have escaped notice but for the hole. The latter was closed with a double purse-string suture and the omentum sutured over this. A posterior gastro-enterostomy, with clamps and suture, was made and the cavity irrigated out thoroughly. The upper wound was closed, but a small suprapubic puncture was made for the draining of the pelvis, and we found that, in spite of the thorough irrigation, there was some fibrin deep in the pelvis, which would have escaped detection otherwise.

The patient made an uninterrupted recovery, and six months later was perfectly well.

No. XLIII. Female, nineteen years old, entered the City Hospital in January, 1900.

Two years before that she had been treated on the medical side for gastric ulcer, vomiting considerable blood at the time. Three months before I saw her she had vomited for several days and had had much abdominal pain. At the end of a week she was well again. Two weeks ago she had a recurrent attack and vomited everything that she ate. She also had considerable pain in the epigastrium, extending to the left shoulder. Since her early attack, in 1898, she had never vomited any blood, but had been troubled with heart-burn, gas, distress, and, at times, pain after eating. In other words she had never been entirely relieved of her ulcer symptoms. The afternoon before entrance she had acute pain in the epigastrium, without vomiting or fainting. She was restless and feverish all night, but in the morning felt better. At entrance she was in good condition, with no distention, but with spasm and tenderness of the left rectus and in the epigastrium.

At operation the peritoneum was found very edematous. Lying close to the anterior wall was a cyst the size of a hen's egg, containing serum, apparently due to peritoneal fluid pent up in the adhesions. A few flakes of lymph were found on the neighboring coils of intestine. At the pyloric end of the stomach close to the lesser curvature was a perforation a quarter of an inch in diameter, through which some curds could be pressed. This ulcer lay in the midst of thick edematous tissue, extending towards the pylorus and half way to the edge of the greater curvature. Any stitches placed in this perforation cut out at once. A crater-like area was then excised and the wound was closed fairly satisfactorily, but the stomach wall was so brittle that it was difficult to invert the edges in order to cover in this line of sutures, so the healthy, lower portion of the stomach below the perforation was turned up and sutured against the line of stitches, completely shutting off the perforation from the general cavity. The abdomen was then irrigated out and the wound closed except for an iodoform gauze and glass drain.

She vomited a few times for several days, but otherwise convalesced satisfactorily and was discharged in about six weeks, with the wound firmly healed and without symptoms.

Nearly four years later she returned to the Carney Hospital with a recurrence of her old symptoms, that is, distress and pain about an hour after eating, vomiting of blood, with temporary relief following evacuation of the stomach. These had returned about three weeks before her entrance and, fearing that she might have another perforation, she sought operation.

At operation in December, 1903, the omentum and the anterior wall of the stomach were found adherent to the parietes and the stomach appeared considerably dilated. Both lobes of the liver were adherent to the anterior stomach wall by old, firm adhesions and deeper by lighter adhesions, the liver being drawn down for an inch or more below its normal level. Over the duodenum and pyloric portion of the stomach there was a light sheet of peritoneal-like adhesions, obscuring this portion of the stomach. The gall bladder was normal. The portion of the stomach adherent to the parietes was approximately in the region of the former perforation. The adhesions here were firm and deep, and after being dissected away, left a raw space that was covered over by a peritoneal flap. A posterior gastro-enterostomy, with clamps and sutures, was made, and the wound closed in layers.

The patient vomited more or less for the first three or four days — some of the vomitus containing digested blood — and she was discharged in three weeks, relieved of her symptoms and feeling well, eating house diet without discomfort and with a good appetite. When seen recently she was in excellent condition, eating ordinary food and working regularly.

No. XCVIII. Female, twenty-one years old, was seen by Dr. Bottomley, with Dr. Thompson of Fitchburg.

The patient had been strong and well up to four years ago, when she had an attack of grippe, with loss of strength, followed a year later by distress after eating, not marked at first, but a year later accompanied by attacks of vomiting lasting from a day to a week. No blood had been seen in the vomitus nor stools. For four or five months she had had epigastric pain, more or less constant, and always after eating.

Forty hours before she was seen by Dr. Bottomley she had a sharp sudden attack of pain, coming on two hours after eating, with collapse, nausea and extension of the pain over the abdomen generally, and into the left scapular region. These symptoms continued for

thirty-two hours before she summoned medical aid. Distention began about twelve hours after the onset of the attack.

At operation there was general abdominal distention, a pulse of 130, temperature 100° and respiration 40, though she did not look very ill. Tenderness was most marked in the epigastrium and to the left. There was general abdominal spasm. On opening the abdomen, gas and large quantities of light green fluid escaped. A perforation, admitting the finger, was found on the anterior wall near the pylorus and fairly close to the greater curvature. About the perforation there was considerable induration, but it could be turned in and closed by a double row of linen purse-string sutures. The peritoneal cavity was washed out, the pelvis drained through a suprapubic opening, and the patient put to bed with the head elevated.

She recovered well from the operation, but died in forty-eight hours of general peritonitis.

Although perforation of an ulcer is rare, the possibility of this accident should be considered as carefully as the possibility of a perforation of an appendix, especially when a previous history pointing to gastric trouble can be obtained. Probably a large proportion of these causes can be cured if they are detected and treated surgically within the first twenty-four hours.

One of my cases would probably have recovered if I had had the wisdom to drain the pelvis, which in such cases cannot be flushed out thoroughly from the upper wound.

All of these cases gave histories of more or less continuous gastric symptoms before the operation. The plea that some cases of perforation recover spontaneously as shown in several of our patients reported in the ulcer series is not worthy of consideration, when contrasted with the relative safety of intelligent, early, surgical interference.

The following case is the only one of pyloroplasty that I have done. It is an operation that nowadays is discouraged as being less efficacious than the more radical procedures.

No. XLIV. Male, thirty-nine years old, entered the medical service of the City Hospital in October, 1899.

Two years before that he began to have epigastric pain after eating, with much vomiting. He was in a hospital in Brooklyn for three or four months, where he improved somewhat. He then grew worse and was in a hospital in Maine for several months, steadily growing worse. At entrance he had pain in the epigastric region, and vomited everything he ate, the vomitus being dark generally, but slightly tinged with blood once or twice. He had lost weight steadily, was very weak, and had much belching of wind. The bowels were constipated. Numerous tests were made of his stomach contents, hydrochloric acid being found present or absent at different times, and so far as the interpretation of the chemical analysis went, nothing definite could be determined as to the presence or absence of a malignant growth. In brief, there was marked stasis and distention, persistent vomiting, with pain in the epigastrium; in addition to this he was steadily losing weight. After about seven weeks of medical treatment he was transferred to the surgical service, much emaciated, with tense abdomen, but without any definite tumor to be felt.

At operation the pylorus was found closed so that it admitted only a director. A pyloroplasty was done and the abdomen closed. No ulcers were found in the stomach or in the pyloric region. He rapidly gained weight and strength and was discharged in a month, eating solid food, with good digestion. A year later, he was seen in perfect health, fat and strong.

This, the only case operated upon by the old method for enlarging the pylorus, illustrates the wisdom of operating in cases, no matter how hopeless the outlook may be. For all that we could tell, the case was malignant, and had it been so, he probably would have promptly died. As it was, he proved to be the most brilliant and satisfactory case that one could desire.

CASES OF PARTIAL GASTRECTOMY.

No. XLV. Male, thirty-five years old, was seen in November, 1901, with Dr. Goodwin of Clinton, convalescing from an attack of acute gastric ulcer and suffering in addition from a mild attack of appendicitis. He quieted down and operation was advised in case of return of the trouble. He gained for a number of months; then, a short time before operation he had a return of his gastric pain and eructations of sour fluid. This was followed by distress, with vomiting, the distress severe in character being located in the epigastric region. Vomiting relieved it temporarily. Three times he had noticed coffee-ground material.

At operation, November, 1902, at the Clinton Hospital, a dilated stomach was found, with a hard, crater-like tumor of the lesser curvature, a little to the right of the middle. There was also an old scar and induration of the pylorus. A partial gastrectomy was done, the proximal third only being left. A button anastomosis was made between the stomach at its lower anterior edge and the jejunum. The omentum was sutured about the joint. The patient was in good condition throughout.

He steadily improved, and in March, 1904, he reported himself as in good health, eating heartily.

Pathological report of the ulcers, which at the time of operation looked suspiciously like carcinoma, showed them to be simple ulcers of the stomach.

No. XLVI. Female, thirty-one years old, referred by Dr. Smithwick.

Eleven years before I saw her she had indigestion, with vomiting, lasting about six weeks. At no time was blood seen. After this more or less stomach trouble persisted, marked by pain in the epigastrium, and indigestion. In 1898 there was a severe attack of pain and vomiting, with some blood, and she went into the hospital for a month and was convalescing for two months. She then worked four months and had another attack, which laid her up for three months, but after that was unable to work for two years. Before I saw her, in August, 1903, she had tried to work for four months, but every day she had epigastric pain with vomiting, and was unable to eat anything except milk and lime water, or malted milk. Vomiting came on within an hour after eating and she said that she had vomited food eaten twenty-four hours previously. She was losing weight, and examination showed local tenderness under the left rectus, which was rigid.

At operation at the Boothby Hospital, in January, 1903, an indurated, puckering tumor in the anterior wall of the stomach, probably involving the lesser curvature, and extending downwards half way to the lower border — almost making an hour-glass contraction — was found. Three bands of adhesions passed

from the stomach near the pylorus to the upper and under surface of the liver. There was a scar at the pylorus, looking like the scar of an old ulcer. The tumor was evidently an ulcer with marked contraction of the adjacent stomach wall. The ulcer was excised, leaving a large opening in the anterior wall. The edges were sutured with catgut to control bleeding, and then the peritoneal edges were closed, in a sagittal line, with a right angle, continuous, linen suture, reinforced by mattress suture. After closure of the stomach there was ample room for passage of food. The abdominal wound was closed in layers with a temporary wick drain down to the stomach suture line, the patient being in good condition at the termination of the operation.

For three days she did well, when suddenly she complained of pain in the abdomen, the pulse rose rapidly to 160, and she died within twenty-four hours.

Partial examination through the wound showed that there was probably a leakage through the stomach wound into the abdominal cavity. Examination of the ulcer showed it to be a simple ulcer and not malignant. This patient died directly as the result of operation. Had a double line of sutures been placed instead of a single line reinforced, as it was, by occasional mattress sutures, the result undoubtedly would have been different.

No. XLVII. Female, thirty-six years old, referred by Dr. Goodwin of Clinton.

For nine years the patient had had indigestion, with gradual development of vomiting, the attacks varying in length, at times being free for a few days. Two months ago she grew worse, vomiting a little while after meals, the vomiting being preceded by severe pain in the epigastrium. There was no history of retained food, and for two weeks she had eaten scarcely anything.

The stomach was found dilated, without evidence of tumor, but with epigastric tenderness.

At operation, at the Carney Hospital, December, 1903, on the anterior wall at the lesser curvature, infiltrating the lesser omentum, was a hard, crater-like ulcer of the size of a silver dollar. No metastases could be felt anywhere. A large section of the upper border of the stomach was removed and the stomach walls closed in with linen sutures. A posterior gastro-enterostomy was then done and the abdominal wound closed in layers, allowing for a temporary cigarette drain at the upper angle. After the operation the patient had no vomiting, was rapidly put on house diet, and in three weeks was discharged, eating and enjoying regular meals.

Pathological report of the ulcer showed it to be chronic inflammatory.

The patient has recently been heard from and is in excellent condition.

The fatal result in one of these three cases was directly the result of an operation badly done. With the recent technical advances the risk has been lowered very much and I feel that in time the more radical operation will be done much more frequently as being conservative in the long run.

To determine the character of the ulcers such as these patients exhibited is impossible without microscopical examination. To err on the side of caution and perform pylorectomy or gastrectomy is wiser than to err the other way, as was done in one of my ulcer cases where death from secondary carcinoma resulted.

UNSATISFACTORY CASES, NOT MALIGNANT.

No. XLVIII. Male, fifty-eight years old, entered the City Hospital in April, 1903.

His illness began with vomiting after a Thanksgiving dinner in November, 1903. The vomiting had continued and increased in frequency until at entrance the patient vomited two or three times a day. He had never seen blood and had complained of but little pain except at the outset. He had lost from thirty to forty pounds in weight.

Examination of the stomach contents showed an excessive amount of residue, absence of free hydrochloric acid and presence of lactic acid. No blood was found. Two days after entrance to the medical service he was transferred to the surgical service for operation, when he was found weak, slightly cyanotic, in poor general condition, with prominent epigastrium and visible peristalsis of the stomach. Some blood was found on a later examination of the stomach contents. The patient was too sick for operation, and for five days was fed on enemata in the hopes of getting him into condition for interference. He had grown stupid and delirious and the operation was done as a desperate resort.

Under cocaine — the patient being too ill for general anesthesia — a loop of jejunum was drawn out and a catheter fastened in, nourishment being given at once. There was some shock even from this slight operation. He was fed frequently through the catheter but steadily grew worse and died of starvation about thirty-six hours after operation.

No. XLIX. Male, fifty-five years old, was operated upon by myself at the City Hospital in 1902, for supposed cancer of the descending colon, when a band of adhesions was found in the left iliac fossa obstructing the sigmoid. These adhesions were evidently of very old origin, and as exploration of the appendix region showed a lot of old adhesions in that location, the diagnosis of old appendicitis was naturally made. Twenty years before that, he had been treated at the Massachusetts General Hospital for acute abdominal inflammation. He was discharged in a short time, relieved of his bowel difficulty, but in October, 1903, he came to the Carney Hospital with an additional history of soreness in his stomach, persisting for years, with vomiting of a foamy substance, occasionally bilious, and vomiting also of food eaten one or two days before, with relief to the pain. He was still constipated, but complained of no symptoms of bowel obstruction. He had been a steady, hard drinker for years.

At operation the loop of sigmoid freed at the previous operation appeared normal. In the duodenum close to the pylorus was a stellate scar, with adherent omentum, dragging the pyloric portion downwards and apparently causing a kink. The pylorus was open and not indurated. The stomach was not dilated. The gastrohepatic omentum was shortened, after freeing the pyloric adhesions, carrying the body of the stomach upwards and relieving the sagging at the pyloric end. The wound was closed in layers and the patient went out, gaining in weight and eating food without trouble.

It is fair to presume that the adhesions in the lower part of the abdomen followed an old perforating ulcer of the duodenum.

No. L. Female, thirty-five years old, referred by Dr. Smithwick.

A neurotic patient with stomach trouble for a number of years, growing worse in the last two years. She complained of much gas, distress, thumping sensation

in the left side, especially, and eructations. Food apparently caused pain. She vomited severely before medical treatment, but under diet had vomited only occasionally. Constipated. Lower border of stomach two inches below the umbilicus.

At operation at the Carney Hospital, a sagging stomach, without evidence of ulcers, was found, the pylorus being relatively high, but open, though irritable. The gastrohepatic omentum was shortened with catgut, lifting the lower border of the stomach nearly up to its normal level, that is to say, almost perpendicular. The abdominal wound was closed in layers.

The later history of this patient has not been obtained, but it is doubtful if she received marked benefit.

No. LI. Male, fifty-two years old, entered the Carney Hospital December, 1903, with an obscure history, suggesting persistent hemorrhage from a duodenal ulcer. He was markedly neurasthenic, moderately alcoholic, and since spring, had had some vomiting, without blood, and had been unable to work all summer. Nothing definite could be found on examination, and exploratory operation was advised.

The stomach was found U-shaped, with a stretched gastrohepatic ligament, not dilated under ether. There was no sign of ulcer. The pylorus admitted the finger easily. The liver was slightly prolapsed. Examination of the abdomen elsewhere was negative except that some large, hard nodes were found near the appendix.

A second incision was made through the rectus over the appendix, which was found small and normal, but in the mesentery opposite the iliocecal valve was a hard gland, with contracted adherent peritoneum, and from this in various directions were smaller, indurated, discrete glands, one of which was removed for diagnosis. Careful search failed to show any evidence of the primary lesion. The gastrohepatic ligament was then shortened, raising the lesser curvature to a normal angle. Both wounds were closed in layers. Pathological diagnosis of the gland removed showed "obsolete tuberculosis presumably."

This patient improved somewhat and was about ready for discharge, when he developed a facial erysipelas, and was transferred to the City Hospital, where he died ten days later of the erysipelas.

These three cases were unsatisfactory, illustrating the unwisdom of half-way measures. It is doubtful if suturing the omentum is enough less serious to make it preferable to more radical operations. Combined with some form of anastomosis it is quite satisfactory.

No. LII. Female, thirty-nine years old, entered the City Hospital in August, 1901, with a history of persistent bleeding by mouth and rectum.

For two years previously she had been troubled with indigestion, but without symptoms as severe as the present. Two weeks before entrance she began to have severe pain immediately upon eating, and tenderness in the epigastrium, but without vomiting. She then limited herself to liquid diet, and forty-eight hours before entrance vomited and passed blood by stools. The vomiting had continued steadily up to entrance and she passed several bloody stools. There was considerable pain. She was markedly pale, with irregular, intermittent pulse, retracted abdomen, and some tenderness in the epigastrium. An operation before collapse had come on was advised.

At operation the stomach was opened and explored with the finger, and although it contained considerable liquid and digested blood no ulceration could be felt or seen, though all of its walls were not examined in the hurry of the operation. A button anastomosis was made and the abdomen closed. The patient, in poor condition at the start, stood the operation well.

The following day she still vomited blood and had five rectal hemorrhages, while the pulse and temperature steadily rose. The following day she had rectal hemorrhages, but without vomiting. Three days after operation she died, and partial autopsy showed that peritonitis at least did not cause death.

No. LIII. TIRRELL: Female, thirty-seven years old, entered the City Hospital, November, 1902.

About a year before this the patient had had uremia following childbirth. Then followed much vomiting, treated by lavage. At times she vomited retained food in large quantities. She entered the medical side and was under treatment for over a month, for dysentery and diarrhea, with relief. Improvement in her gastric symptoms followed lavage, but there was no gain in weight, and recently there had been a relapse of vomiting of large amounts of undigested food, but without blood. The patient was in poor condition, emaciated, and with plainly visible peristalsis.

The gastric contents showed no free hydrochloric acid nor lactic acid. The stomach, apparently dilated at entrance, resumed its normal limits gradually, but in spite of that, the symptoms referred to grew worse and she was transferred to the surgical service for operation.

At operation there was no distention of the stomach, but the small gut was distended; there was marked spasm of the pyloric end of the duodenum, practically closing the lumen for several inches; no tumor nor scars were found, while a hurried examination of the abdominal cavity failed to show anything definite, the patient being too ill for extensive search. An anterior button anastomosis was made, the joints being reinforced with omentum. The wound was closed in layers. The patient came out of the ether well, but failed rapidly and died within twelve hours.

Partial autopsy showed tubercular colitis and tubercular ulcer of the duodenum.

No. LIV. Male, twenty-nine, entered the City Hospital in May, 1903.

The patient was a hard drinker and came in with delirium tremens. Eight years before entrance he is said to have had an attack similar to the present one, lasting four weeks, vomiting blood three times during the attack. Six weeks before entrance, after hard drinking, he vomited blood and was in an out-of-town hospital for a week, with cessation of vomiting at the time of discharge. Four days before entrance he had epigastric pain, but without vomiting of blood. There was marked tenderness in the epigastric region but under low, mild diet and rest the patient improved. Unwisely, operation was advised and performed. Nothing but thickening of the pylorus — but with free opening — was found. A posterior gastrojejunostomy by Mikulicz's method was done and the wound closed in layers.

The patient relapsed into his alcoholic condition a few days after operation, became delirious, cynotic, and died four days after operation. This patient should have been left alone.

No. LII died as a result of operation done early in my series when the technic was much less simple than at the present time.

No. LIII was hardly a case for interference and operation was offered as a last resort.

No. LIV should never have been touched. It was bad judgment to have attempted anything surgical.

No. LV. Male, fifty-three years old, referred by Dr. Pierce of Norfolk Downs.

For a number of years he had had epigastric pain, and a year ago began vomiting after supper. Six months later the vomiting attacks came on more often and five days before I saw him he had had copious vomiting, preceded by severe gastric pain. Always constipated. The amount of vomitus was excessive. He had never noticed blood nor coffee grounds. He had lost much weight and recently had lost much strength.

Examination showed a retracted abdomen, with dilated stomach, but without definite tumor.

At operation, December, 1902, at the Quincy Hospital, in the front wall of the pylorus and extending in under the surface, were old scars and adhesions. The tissues about the pylorus formed a swelling the size of a hen's egg, but without induration, like a malignant growth. The pyloric opening was practically closed. This mass was adherent to the right lower edge of the lesser omentum, the duodenum lying behind some sheets of peritoneum that were apparently adhesions. The duodenum was freed and a gastro-duodenostomy by Finney's method was done. The pylorus was so adherent that, in trying to separate it, the cavity was torn into and had to be temporarily closed with catgut. Abdominal wound closed, allowing for a temporary wick drain to the line of sutures. Patient in good condition at the close.

He vomited more or less for a day or two after operation and inhaled some vomitus, which started up a bronchitis, to which he rapidly succumbed. Examination through the wound showed no peritonitis.

Although this patient died from inhalation pneumonia the operation must take the blame for the result. At present, I am sure the outlook would be far more favorable.

No. LVI. Male, forty-five years old, referred to me by Dr. Lawrence of Brockton.

Three years ago he had an attack of pain in the stomach, without vomiting, lasting for three months. A year later he had a return of the symptoms, lasting the same time. One year ago the symptoms returned for the second time and persisted up to the time that I saw him, in September, 1903, when I found pain in the left loin and hypochondrium, with eructations of gas, relieved by the use of the stomach tube for the last two or three months. For over a year, after eating anything he had complained of pain, lasting two or three hours, without nausea, and he had been very much constipated for months. He stated that a year ago he had tarry stools. When the pain in the stomach began he would lie down with relief. There was no history of retained food. He had lost much weight in the last year. There was some dilatation of the stomach, with slight tenderness, and, possibly, thickening under the left hypochondrium. Nothing suggestive of an aortic lesion was found in examination of the chest, and hence the aneurism from which he died was entirely unsuspected.

Examination of the stomach contents showed absence of free hydrochloric acid and much diminished combined hydrochloric acid.

At operation, at the Carney Hospital, the liver and stomach were both found prolapsed, with a slight thickening at the pylorus. The gastrohepatic omentum was shortened and a posterior gastro-enterostomy, with clamps and sutures, was made. A little blood was found within the stomach at the time of operation. The liver was sutured up into place, and the wound closed in layers. The patient progressed satisfactorily and was beginning to eat, when, five days after operation, he suddenly vomited up a large amount of fresh blood and died.

Autopsy showed a ruptured aneurism of the thoracic aorta, emptying into the pleura. There was no gastric ulcer to be found.

No. LVII. Male, sixty-five years old, had suffered from stomach trouble for six years, beginning with sharp, stabbing pain in the right side. He had vomited much and thought he had vomited coffee grounds. He had lost much weight in the last six months and was unable to work. On entrance to the Carney Hospital, in October, 1903, he was markedly emaciated and starved. Operation was urged to prevent death from starvation if possible.

At operation, in the region of the duodenum and gall bladder there was a general mass of old adhesions, the gall bladder being so covered over that it was not distinguishable. In the adhesions were old scars as though from a perforating ulcer. Nothing abnormal was felt in the stomach or elsewhere in the abdomen. The pylorus when relaxed admitted the finger, but it quickly thickened spasmodically and formed a hard, nodular tumor. A posterior gastro-enterostomy, with clamps and suture, was done and the wound closed. After operation the patient continued vomiting more or less steadily, growing weaker, not deriving any benefit from his rectal or stomach feeding, when, finally, the vomiting became persistent and ten days after operation he died.

Examination through the wound showed that there was no peritonitis nor obvious cause for death.

The outcome of this case was not anticipated before operation. It may have been a case of "vicious circle," but as we watched him it seemed more like death from prolonged starvation from which the patient was too weak to react. Technically the operation seemed most satisfactory, but in the light of a few other bad results it is fairer to ascribe the result to some operative defect.

No. LVIII. A boy three months old, entered the Carney Hospital in November, 1903. Referred to me by Dr. C. W. Townsend, who has reported the case in full in the Boston Medical and Surgical Journal for Feb. 11, 1904.

A brief history of the case showed almost persistent vomiting, with occasional intervals, from the time he was three weeks old, progressive emaciation and starvation, and a dilated stomach. Operation was advised as a last resort.

The stomach was found dilated, and the intestine collapsed. At the pylorus was an oval, fibrous, solid tumor, half to three fourths of an inch in diameter, apparently almost or completely obstructing the lumen. A posterior gastro-enterostomy, with clamps and sutures, was done, the omentum and mesocolon being found mere films, without trace of fat. Wound closed in layers. The baby recovered from the operation and seemed to hold its own, taking small amounts of hot water by mouth and retaining this fairly well, but eighteen hours after operation it vomited about four ounces of digested blood and bile and collapsed. Later it vomited more dark blood and bile and died twenty-four hours after operation.

Pathological report showed a hypertrophy of the pylorus, with the associated narrowing of its lumen.

This case suggests strongly the wisdom of early interference in infants with persistent vomiting not explainable on dietary errors. In such cases

the operation is probably very safe, and it is most probable that these cases are more common than the general practitioner realizes.

No. LIX. Male, twenty-six years old, was seen with Dr. McCook at Hartford a short time before operation. The history obtained at that time pointed to acute gastric ulcer, and operation was advised. The full history obtained later, through the courtesy of Dr. McCook, is as follows: Nine years before he had had a sharp attack of indigestion with vomiting and abdominal pain. In 1898 he was in bed three months with inflammatory rheumatism, and for the following six months he had a number of fainting attacks. In 1899 there was cough and expectoration, for which he went to Kentucky. He recovered and remained well until seven weeks before I saw him, when diarrhea began, lasting a couple of days, followed by vomiting, which had persisted up to the time of operation. The vomiting came on at variable times after eating, and he could hold nothing on his stomach except hot milk. Constipation was marked during the attacks of vomiting. For two weeks he had complained of dull pain in the abdomen, with occasional sharp pain in the right epigastrium. Once he noticed some bright blood in the vomit and had noticed, also, dark stools. There was slight tenderness over McBurney's point, loss of weight, and a normal white count and urine. Stomach contents showed absence of hydrochloric acid and presence of lactic acid, absence of blood, a little mucus and some bile. At consultation, when I saw him, the diagnosis lay between gastric ulcer, with pyloric obstruction, and a gastric neurosis.

At operation at the Hartford Hospital, an exploration of the gall bladder and appendix regions, etc., were negative. No ulcer could be felt in the stomach. The pylorus was open. Nothing could be felt in the duodenum. A posterior gastro-enterostomy was made by Mikulicz's method and the abdominal wound closed.

There was no shock following the operation, but vomiting began at once. He was kept on rectal feeding for five days. Then boiled water was given him by mouth, which he vomited at once. Delirium then began and continued until death, eight days after operation. On removal of the silkworm gut sutures a small stitch abscess was found. Otherwise the wound healed well. The temperature rose at once after operation and continued at about 101° until just before death, when it rose to 104°. The pulse, 90 to 100 for the first week, rose to 120 and thence higher until death.

An examination was allowed only through the wound. A little bloody serum was found in the abdominal wound. There was no peritonitis. The joint was tight. No ulcer of the stomach was found and no pyloric stenosis. The kidneys were slightly congested, and there were a few new adhesions (probably from operation) near the umbilicus. The appendix showed chronic inflammation, the tip being under the border of the ribs; and from the appendix an old fibrous band extended to the side of the abdomen under the liver, which looped up the appendix. The exact insertion of this band could not be made out with the limited incision permitted. Unless this band from the appendix, which was overlooked at the time of operation, was the cause of the vomiting, through constriction of the gut, there is no way to explain the symptoms nor the cause of death. The intestine at operation was not distended, but as in case No. 67 it may be possible that the vomiting was reflex from the dragging of the small gut, but without constriction sufficient to produce obstruction.

No. LX. Female, twenty-eight years old, entered the City Hospital in September, 1901. For a number of years she had had stomach trouble, with vomiting an hour or two after eating, nausea and epigastric pain. This had persisted up to the present time. Three years ago she had a severe epigastric attack, vomited blood after eating and passed blood by rectum. This attack was repeated two months, three weeks, and four days, respectively, before she entered the Hospital. There was a history of vomiting retained blood. Almost every night after midnight she would vomit excessive amounts. She had lost weight, and for nine months there had been marked tenderness in the epigastrium. Recently she had noticed a bunch in the same region. Analysis of the stomach contents showed dilatation, stasis, free hydrochloric acid, and a small amount of lactic acid. She had previously had a laparotomy for ovarian trouble.

At operation the omentum was found adherent to the old laparotomy wound. The stomach showed nothing definite on the outside. A posterior anastomosis was made with silk and catgut by the old method. Exploration showed that the pylorus admitted the finger and no ulcers could be felt on either wall. Abdominal wound was closed. After operation she vomited somewhat but less than before, and nearly three weeks later developed a phlebitis of the left leg. A month after operation, as she still had occasional vomiting, the stomach was washed out and analysis showed that there was still dilatation and stasis, no blood, no free hydrochloric acid, and diminished combined hydrochloric acid. Two months after operation she was discharged, a little improved, having refused to have any further interference. Taken in conjunction with several later cases the possible effect of an omentum adherent to the scar of a former laparotomy must be considered in diagnosticating gastric lesions.

No. LXI. Female, twenty-eight years old, was referred to me in October, 1902, by Dr. Smithwick. She was a neurotic woman, nearly unbalanced mentally, and the entire history must be taken with considerable latitude.

She had complained for five or six years of headache and constipation without definite stomach symptoms. She had never had vomiting, nor lost weight, and complained more of general debility and constipation than anything. Examination showed dilatation of the stomach. As there was a fairly definite specific history the patient was put on iodide of potash and operation advised against. In August, 1903, she returned again, having received benefit from the iodide for a while, followed by relapse, with symptoms worse than ever. An exploratory laparotomy on the basis of probable ulcer of pylorus was advised, but not urged.

At operation, at the Boothby Hospital, the stomach was found dilated. At the pylorus, on the proximal side, and extending for about an inch in the greater curvature, marked induration could be felt. In the lesser curvature was a small nodule suggesting another ulcer or scar. The pylorus itself was not narrowed. There were large lymph nodes along the lower border. Elsewhere the abdomen was negative. A posterior gastro-enterostomy by Mikulicz's method, but using clamps to control hemorrhage and leakage, was made. The abdominal wound was closed in layers. She convalesced well, had no nausea, and was discharged about ten days after operation.

Later it was learned that the symptoms had relapsed and that the operation had been of no benefit, as might have been anticipated from the first. At present she is receiving marked benefit from the treatment of one of our irregular practitioners and considers herself nearly well.

Medical Progress.

PROGRESS IN GASTRO-INTESTINAL DISEASES.

BY ELLIOTT P. JOSLIN, M.D., BOSTON.

(Concluded from No. 6, p. 163.)

COMPLETE REMOVAL OF THE STOMACH.

THE following is taken from a review of Boeckel's [7] book on "De l'Ablation de l'Estomac." At the date of publication the number of cases reported was 48 and of these the result was unknown in 2. Of the remaining 46, 18 died and 28 recovered, giving a mortality of 39.1%. In 9 cases collapse was the cause of death, in 7 purulent peritonitis, and in one pneumonia. Seven of the 28 patients who have recovered are not available for a final report. Of the remaining 21, 11 have died of recurrence after an interval varying between five months and five years; one died of intestinal obstruction without recurrence seven and a half months after the operation and another in two years of phthisis. Eight of the patients still enjoy the best of health. In the duodenum near the gastro-intestinal anastomosis a pouch forms which gradually dilates and to a certain extent acts as a new stomach. Digestion goes on without disturbance and there is a gain in weight. The reviewer strongly recommends Boeckel's book.

SUBCUTANEOUS FEEDING WITH FAT.

Winternitz [8] reaches the following conclusions as the result of a series of experiments in which fat was subcutaneously injected. Fat so administered is absorbed and used in the metabolism. In the course of time absorption is complete, but the quantity of oil absorbed after an injection of five hundred gm. within five days does not exceed 2 gm. to 3 gm. per day; indeed during the first week the daily amount absorbed is notably less. Consequently, months pass until complete absorption takes place. Therefore, from his experiments, Winternitz concludes that the fats are not adapted for subcutaneous feeding.

THE INFLUENCE UPON FAT OF GASTRIC DIGESTION AND THE TREATMENT OF HYPERACIDITY.

It is known that fat and sugar solutions will diminish the secretion of gastric juice. According to Pawlow this is brought about reflexly by the contact of the fat with the mucous membrane of the duodenum. Clinically, Aldor and Strauss found that butter and cream caused a lowering in the amount of free hydrochloric acid as well as of the total acidity and so recommended these foods as the best dietetic treatment of hyperacidity of the stomach. In a similar manner other observers have shown that the addition of fat to the diet not only decreased the amount of hydrochloric acid, but the quantity of gastric juice as well. Buch demonstrated this in hyperacidity. As a rule milk fat has been used therapeutically, but various authors have shown the equally good effect of olive oil. Influenced by these facts Walko [9] has made a systematic study of the question. His experiments were of the following character: A test meal consisting of 100 gm. bread and 400 cm. water was given, and the free HCl. and total acidity determined after a given interval. On another occasion the same meal was repeated, but this time with the addition of oil varying in quantities from 50 cm. to 100 cm. The analyses showed that the olive oil in the small as well as in the large doses delayed the secretion and at the same time confined the per cent of acidity within lower limits than was the case when no oil was administered. Clinically it was of interest that the large doses of oil did not necessarily mean a much larger decrease in acid than small doses. It is true that these amounts of oil delay digestion or rather cause the meal to remain one to one and a half hours longer in the stomach. However, it should be borne in mind that the oil remains no longer than would carbohydrates or proteids of equal nutritive value. And further the delay is not proportional to the quantity of fat given.

Much interest has been taken in recent years in the digestion, or more precisely the splitting up of neutral fat in the stomach. Evidence has steadily accumulated to show that the gastric juice is not passive in this regard. Walko proved that even as much as 77% neutral fat might be broken up into fatty acid by the gastric juice. The amount of fat splitting ferment in the stomach is greatest with a milk diet, less with meat and least of all with carbohydrates. Walko also studied the interesting question of the influence of olive oil on the simultaneous digestion of other foods in the stomach. His results are convincing that the oil decidedly favors the digestion of proteids and starches. By its action the extra quantity of starch converted into sugar is directly favorable to the treatment of hyperacidity as sugar is known to decrease the secretion of hydrochloric acid.

Bone marrow from its high content of fat acts similarly to olive oil and is therefore strongly recommended by Walko.

The clinical results obtained by Walko more than fulfilled the expectations which the experiments, above cited, suggested. In hyperacidity of the stomach, the acidity was lowered and the symptoms abated under the administration of the oil in doses of 20 cm. to 200 cm. given through the tube, or simply drunk by the patient. The oil was given a few mornings in succession after the test breakfast had been thoroughly removed. Concurrently the constipated bowels became loose, but, after a few days, regular, and the patient gained in weight. In dilatation of the stomach with hyperacidity the oil worked remarkably well. The acidity decreased, the motor function improved and with it the gain in strength and, as above, the bowels became regular. Walko further recommends the use of oil in ulcer of the stomach

because of its unirritating qualities, its high nutritive value, its restricting influence on the hydrochloric acid secretion and its cure of the constipation.

The remainder of the article is devoted to the discussion of the action of atropin, bicarbonate of soda and Carlsbad salts in the treatment of hyperacidity, and an analysis of the evidence in favor of a carbohydrate or proteid diet. He reaches the conclusion that the fat diet is the preferable method of treating the condition.

Reports of Societies.

AMERICAN SURGICAL ASSOCIATION.

PROCEEDINGS OF THE TWENTY-FIFTH ANNUAL MEETING, HELD IN ST. LOUIS, JUNE 14, 15, 16 AND 17, 1904.

(Continued from No. 6, p. 166.)

REMARKS UPON CERTAIN UNAVOIDABLE POST-OPERATIVE CALAMITIES IN ABDOMINAL SURGERY.

DR. MAURICE H. RICHARDSON of Boston read a paper with this title, which was based upon his experience more especially in abdominal surgery, and related exclusively to fatal cases. Four classes of calamities were considered: (1) Suppression of urine; (2) inexplicable deaths, with symptoms of local and general sepsis, but without any detectable bacterial source; (3) uncontrollable capillary hemorrhage; (4) pulmonary embolism.

Suppression of urine could be regarded as an unavoidable accident only when it took place after the urine had been shown to be normal by the most searching study. The influence of ether alone in causing suppression after operations was not regarded as sufficient and sole cause of this calamity. It was doubtless true that failure of the kidneys properly to perform their function was due to some pathological change in the secreting substance; if not a pathological change, a tendency to glomerular irritation or real inflammation, but a change or tendency which could not be detected beforehand. Such suppression of urine, however, might be prevented by the avoidance of all but imperative operations whenever there was the least evidence of renal disease, especially an insufficiency in the elimination of urea. Renal suppression was not believed by the writer to be the result of etherization alone.

In certain very rare instances death had taken place after abdominal operations without any pathological cause whatever. In one illustrative case, after an aseptic, though difficult and bloody operation, the patient presented the typical clinical picture of fatal general peritonitis. The pathologist at the Massachusetts General Hospital could find no evidence whatever of bacterial infection at the autopsy or in the laboratory. That there was an infection the essayist had no doubt, but by a germ which produced none of the usual physical signs of sepsis, which failed to grow on ordinary media.

Uncontrollable capillary oozing might be regarded as unavoidable, and beyond the power of prediction only when it took place after careful examination of the blood with reference to its coagulability, and other possible evidences of a tendency to bleed. Capillary hemorrhage from jaundice might be in certain instances uncontrollable. It could be regarded as uncontrollable only when operation must be performed in spite of the evidence of the tendency to hemorrhage. The coagulation tumor did not reasonably assure safety against bleeding, even if it was shown experimentally to be brief. The author's last fatal hemorrhage in jaundice took place from the capillaries of the lesser curvature of the stomach, remote from the operation area, though the blood coagulation tumor was perfectly satisfactory. In another case a fatal and uncontrollable capillary ooze followed an operation upon the common duct after a year of biliary fistula. In this case no bile had entered the intestine during the existence of the biliary fistula. The most frequent of such rare calamities was sudden death from pulmonary embolism. The cause of death could neither be predicted nor prevented. It occurred with no peritonitis. The probability of embolism being the result of a phlebitis was considered. In the author's experience, in a considerable number of deaths there were no premonitory symptoms whatsoever, while in cases of phlebitis, definite and unmistakable, no such accident occurred. Pulmonary embolism had been observed most frequently after pelvic operations upon women with large uterine or ovarian tumors, and especially in women long exsanguinated by fibroids.

PAPILLARY CYSTS AND PAPILLARY TUMORS OF THE OVARIES, WITH CONSIDERATION OF PROGNOSIS AND TREATMENT.

PROF. SAMUEL POZZI of Paris, France, read a paper on this subject, in which he summarized as follows:

"1. Papillary tumors of the ovary, cystic or solid, must not be considered as always malignant. Some of these tumors never undergo malignant degeneration, and do not relapse after removal. Some relapse after a long time, and locally without metastases.

"2. A careful distinction must be made between carcinomatous generalization, which takes place through the lymphatics and blood vessels, and simple grafts which result from contact or from the growing over the peritoneum of detached papillary vegetations of the ovary. This process is benign and can be compared to the grafting of papillomas and warts of the skin.

"3. Some of these tumors undergo a malignant degeneration which is for some time limited, but can later extend all over the mass, and which at last brings on a real generalization with cancer metastases. Before this last period, and at the outset of the malignant transformation, it is quite impossible to discern it with the naked eye, and microscopical investigations are needed. The prognosis is always uncertain in operations of this kind before a thorough pathological examination. Even such examination may lead to misinterpretation, if it has not been carried all over the tumor, for the degeneration may be limited to a small part of the growth.

"4. When positive symptoms of malignancy are absent, such as cancerous cachexia, or visceral metastases, operators must always treat these tumors as if they were benign, and proceed to remove, to the largest extent possible, the neoplasm. The disseminated growths or even small parts of the papillary tumor detached and lost in the peritoneal cavity may disappear. In other cases they may be the origin of local recurrence. But these relapses can be treated successfully by secondary operations.

"5. Frequency of successive invasion of both ovaries by papillary tumors furnishes an indication to remove the adnexa on both sides, even if one is still healthy, at least in women who are near the change of life. In young women it would be better to preserve a non-diseased ovary.

"6. In bilateral papillary tumors the operative technic can be greatly improved by performing partial or total hysterectomy, according to the case.

"7. Drainage is not necessary when the cysts have no outside vegetations, and when there is no ascites. But in case ascites exists for some time, it would be well to drain the peritoneal cavity. Incomplete removal, or even an exploratory section, in unoperable cases, is often accompanied by a real diminution of ascites, with local and general improvement."

ANKYLOSIS TREATED BY ARTHROPLASTY, CLINICAL AND EXPERIMENTAL.

Dr. John B. Murphy of Chicago spoke on this subject. He mentioned three types of ankylosis, namely, ankylosis from periarthritis, ankylosis from capsular lesions and bony ankylosis.

Bony ankylosis could be relieved. Tissue could be interposed to prevent the re-establishment of bony union, and with the recognition of the changes which occurred in fat close to the aponeurosis, a joint could be produced with a serous-secreting surface. His experimental work had shown that after the removal of the hip joint in a dog, cartilage, synovial membrane and the articular surfaces in their entirety, with replacement of tissue in the acetabulum, and replacement of bone again, he had produced a typical synovial membrane in the sense of a hygroma. In the production of hygroma pressure on fatty tissue had a tendency to bring about a coalescence of the small fatty capsules. The shaft of these capsules produced a serous secretion, and there was developed a condition which was seen in housemaid's knee, over the trochanter of the boiler-maker, and over the wrist of the stonecutter. A serous-secreting surface was brought about. This could be done in a joint. The surgeon could restore joints to practically their normal condition.

The first case he reported was one of bullet wound of the abdomen. The bullet passed through the abdomen a little to the right of the median line, passed across the abdomen, perforated the intestine eight times, fractured the head of the femur, lodged in a pocket, remained there, worked its way out through ulceration, and was finally voided through the intestine. The wounds in the intestine were sewed up, and the patient recovered, with a sinus. The speaker saw the patient with ankylosis of the leg at right angles. He passed around a skiagraph which showed bony union. After removing the head of the femur transperitoneally, curetting and removing the bony debris from the ilium, the wound was allowed to heal, and a plan was devised for the restoration of the joint and the relief of deformity. He decided that it was necessary, first, to expose the joint and to secure bony tissue for the new head. Second, it was necessary to interpose between the fragments not only muscle, but fascia, covered with fatty tissue, because the fatty tissue here, subject to pressure, like the fascia lata of the trochanter, formed hygromata. A U-shaped flap was made, carrying with it fascia lata and all the superficial tissue and skin, then the joint sawed from around the trochanter major. None of the muscles was divided. A circular chisel was used to chisel out the bone in all directions, and with the assistance and leverage of the femur and chisel, a fracture was produced at the base of the cavity, and the head, which was new bone formation, as the original head was removed, was thrown out in connection with the neck, rounded off with bone-cutting forceps, and curette used to enlarge the cavity. The next step of the operation was to separate the fascia lata with its fat and a few fibers of the gluteus muscle; a flap was swung in behind the muscular attachments, and the trochanter major put in around the head of the femur and sewed to the neck. The neck was made short to prevent reunion of the fibrous portion of the capsule which remained, because if the capsule remained in its fixed position, the ankylosis would continue, and this was one of the practical points he derived from this particular case. The trochanter major was sutured to the neck, the head replaced, the trochanter major rounded off, the flap turned down, and the wound drained. The result of the operation was ideal. Dr. Murphy passed around a photograph showing the patient as he stood in the erect position, and the degree of flexion obtained at the end of four months after operation. The patient now had perfect motion and flexion.

He mentioned other cases on which he had operated by this method, with gratifying results. The method was largely intended for the treatment of joints with ankylosis.

NEW AIDS IN DIAGNOSIS OF SURGICAL DISEASES OF THE KIDNEY AND THEIR VALUE.

Dr. A. T. Cabot of Boston read a paper on this subject. His conclusions from the experience he had had and from his study of the work of others were that segregation of the urines was of great use sometimes in deciding the question as to which kidney was diseased, or even as to which was most affected. Determination of the functional capacity of the kidney by testing the elimination through it might be of assistance by adding strength to what evidence we had, but would be often misleading if too implicitly relied upon for deciding operative measures.

REPORT OF A CASE OF ACUTE PANCREATITIS ASSOCIATED WITH GALLSTONES.

Dr. James Bell of Montreal said that the demonstrated facts in his case were: (1) That in March, 1898, there were all the characteristic lesions, as well as the signs and symptoms, of acute pancreatitis, and at the same time an apparently quite healthy liver and gall passage, with two or three stones in the gall bladder. (2) That all signs and symptoms of pancreatitis disappeared, the patient recovering, and considering himself quite well until nearly two years later, when a new train of symptoms developed, which were characteristically those produced by gallstones. (3) Three years after the attack of acute pancreatitis it was demonstrated that while extensive and serious pathological changes had taken place in the gall bladder and bile ducts, all local signs of acute pancreatitis had, during the same period of time, entirely disappeared (subperitoneal fat necrosis and swelling of the pancreas); that was to say, that acute pancreatitis developed before there were any pathological changes in the gall bladder and bile ducts, and that while such changes were taking place, the pancreatitis was recovered from.

These facts would seem to be at variance with modern views of the etiology of acute pancreatitis which tended to attribute this condition in a general way to a pathological change in the common bile duct due to the passage of gallstones from the gall bladder to the intestine.

TREATMENT OF CONGENITAL CLEFT PALATE: A PLEA FOR OPERATIONS IN EARLY INFANCY.

Dr. Truman W. Brophy of Chicago read a paper, by invitation, on this subject. After referring to the work of Lamonier, Kirmisson, Roux and many others in this field, the essayist stated that after having studied carefully the literature and the methods pursued by other operators, he had endeavored to over-

come the objections and to avoid the difficulties with which the older surgeons contended, and he was satisfied that the most desirable time to select for operating was within three months after birth. In operating at that time one was able to secure more satisfactory results than later in life, and avoided the objections usually raised by surgical writers. He believed in operating at as early an age as practicable after birth, preferably within three months, and his experience of twenty years in operations performed for the closure of cleft palate, at from ten days to fifty years of age, including 927 operations, had more and more justified the practice.

Among the advantages mentioned in favor of early operations were the following: Surgical shock was less because the nervous system of a young child was not well developed, and it was not, therefore, capable of receiving the same impressions that it would late in life. Furthermore, young children usually reacted better. All mental apprehensions were eliminated, and alarm and dread were among the most powerful factors in producing shock. Following early operations there was much less deformity, for all the tissues, bony as well as soft, developed naturally and according to accepted types. When the operation was postponed for a few years, it was very difficult to secure as good results. When the operation was made in early infancy, the parts were sufficiently developed to give possibility for normal speech when the child had reached a speaking age.

The author described his method of operating on cleft palate in detail, a description of which has heretofore been published in both dental and medical journals.

In conclusion, the author stated that if operations were made later in life the patient should be placed under the instruction of one who had the perseverance, the ability and patience to teach him how to overcome the defective speech which he had acquired.

THE EVOLUTION OF SURGERY.

DR. J. EWING MEARS of Philadelphia read a scholarly paper with this title. He divided this unfolding of surgery into three periods of time: (1) That which extended from the beginning to the time of Ambroise Paré, 1517–1519; (2) the use by John Collins Warren (1846) of ether as an anesthetic in surgical operations, and (3) the discovery and introduction into general use by Sir Joseph Lister (1860–1875) of the antiseptic treatment of wounds. Each period was taken up and considered in a masterly manner.

(To be continued.)

Recent Literature.

Air, Food and Exercises; an Essay on the Predisposing Causes of Disease. By A. RABAGLIATI, M.A., M.N., F.R.C.S. Edin., Honorary Gynecologist, and Late Senior Honorary Surgeon, Bradford Royal Infirmary; Consulting Surgeon to Bingley Hospital, to Bradford Children's Hospital and to the Bradford Home for Cancer and Incurables. Third edition, greatly enlarged and almost entirely rewritten. New York: William Wood & Co. 1904.

The author says in his preface that "this book is, then, written frankly for the public, in the hope that its perusal may simplify and clarify their ideas upon the subject of disease." That it has reached a third edition would indicate that it has had readers and that the public after two editions, is still in need of clarification.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 18, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

THE BRITISH MEDICAL ASSOCIATION.

THE seventy-second annual meeting of the British Medical Association was held at Oxford, and, so far as one may judge from the reports which have come to us, the meeting was peculiarly successful from every point of view. Not a little of the interest was derived from the fact that Oxford was chosen as the place of meeting, for the first time since 1868, a period during which many changes have taken place at the university, and particularly in those branches of science connected with the early training of the medical student. Dr. William Collier, who delivered the president's address, took for his subject, "The Growth and Development of the Oxford Medical School," and discussed the historical development of medical work at Oxford in a way which must be of interest to physicians outside of the United Kingdom. Dr. Collier is of the opinion that the university has been benefited by the establishment of the medical school on a modern basis, and particularly he finds the influence of the university student on other medical students of the metropolitan schools of very distinct benefit. It is in general the question of a preliminary university training to which so much attention has of late years been given in this country. Considering the previous meetings of the association in Oxford, Dr. Collier called attention to the fact that in 1835 the association brought together 300 members at Oxford; a second meeting, numbering 1,630 members, was held in 1852. In 1868 the association visited Oxford for a third time, the membership having risen to 3,672. Now the membership of the association is upwards of 19,000, when for the fourth time it has met in Oxford.

Sir William Selby Church gave the address in medicine on the important topic of "Our Sanitary Needs with Special Reference to the National Health." The address was in a measure retrospective, but brought out the important present day necessity of increasing attention to the laws of hygiene, both in urban and rural districts, begging finally that the British Medical Association would use its influence to impress both the public and the government with the desirability of a physical census of the nation being taken from time to time, and the necessity of the registration of the physical condition of children on whom the future depends.

The address in surgery by Sir William Macewen was eminently practical in its bearings, taking up in the first place the important question of the localization of brain abscess arising from primary pyogenic cranial lesions, a matter concerning which no one could speak with more authority. Few matters in cerebral surgery are more important than this, owing to the absolute necessity of a correct diagnosis, and the possibility of an immediate and complete relief. We commend the succinct statements made in this connection to aurists and other surgical readers. The remainder of the address was taken up with a discussion of a respiratory and cardiac reflex, and to the choice of ligature and suture material, the latter a matter upon which Mr. Macewen's opinion will be welcome.

An innovation at this meeting of the association was the introduction of a popular lecture, given in the town hall by Dr. Ferguson, attended by a large and appreciative audience. Dr. Ferguson spoke in a practical fashion upon disease germs, and described in language easily comprehensible to the uninitiated certain facts regarding the life history and the effects of various organisms. This plan, adopted this year for the first time, as we understand, by the British Medical Association, is worthy of imitation. That the laity should know certain facts regarding medical matters and hygiene is becoming more and more apparent, and that such knowledge should come through the auspices of a recognized medical body is also fitting.

The honorary degree of D.Sc. was bestowed upon the following physicians: Dr. Clifford Allbutt, Mr. Andrew Clark, Dr. T. D. Griffiths, Mr. Jonathan Hutchinson, Sir William Macewen, Sir Patrick Manson, Sir John William Moore, and Dr. William Osler. Professor Love of the University of Oxford, in presenting the degree to Dr. Osler, spoke as follows:

Among those who apply the results of modern science to the investigation of the causes and the cure of diseases, few have attained greater distinction than William Osler. By his professionial teaching, first in Montreal, and afterwards in Baltimore, by his writings, which deal partly with questions of abstract science and partly with questions concerning the practice of medicine, by his skill as a physician, he has been for many years a leading exponent of the principle that the art of medicine should be based upon the most exact scientific knowledge of the day. For his work in exemplifying this principle, as well as for the merit of his contributions to science, he was elected a Fellow of the Royal Society. In him also we welcome a representative of one of those daughter States which are the pride of the mother country — the Dominion of Canada — and also of that great Republic of the West whose people, bound to us by the closest ties of kinship, are also among our best friends.

AN OUTBREAK OF TYPHOID FEVER.

A SERIOUS outbreak of typhoid fever has occurred in what is known as the Bedford Park section of the Borough of the Bronx, New York, and it is stated that as many as forty-two cases have been discovered in one block. The existence of the trouble had been known for some little time to the Health Department, which had been carrying on an investigation quietly, in order not to unnecessarily alarm the people of the neighborhood; but it was not until Aug. 9 that the facts were made public. On that date a corps of fifty medical inspectors was detailed for the work of preventing the further spread of the disease. It appears that the outbreak has been successfully traced to a spring, the waters of which form a creek which flows through the great reservoir for Croton water, now in process of construction on the site of the old Jerome Park race-course. All of the typhoid patients, it is said, partook of this water, which has been shown to be contaminated. It is a rural neighborhood, and many of the residents have never had the Croton water in their dwellings, and depended entirely on the spring water for cooking and drinking purposes. In many instances, also, the houses have not been connected with the city sewers and have cesspools in their rear. A considerable number of the cases are among Italians, of whom there is a colony of over a thousand persons, the men of the families being engaged in work on the new reservoir.

This epidemic, which no doubt will be speedily checked, is another example of neglect of proper precautions, as all of the recent typhoid epidemics have been. It also shows that, complete

as our knowledge is of the methods of dissemination of this disease, an absolutely constant vigilance is requisite to prevent its appearance in epidemic form.

ANNUAL ENCAMPMENT OF THE GRAND ARMY OF THE REPUBLIC.

BOSTON this week is the center of unusual midsummer activity owing to the presence in the city of the national Grand Army of the Republic encampment. This is presumably the last time that Boston will have the opportunity of seeing face to face the men who took part in the Civil War. Young as many of the soldiers were who enlisted and fought during the period from 1861 to 1865, the lapse of time has led to the inevitable result that many who are left are far advanced in years and show the decrepitude which comes from age as well as from wounds and injuries received in active service. Inspiring, therefore, as this occasion is likely to prove, there is associated with it a sense of sadness in that the actual participants in the War of the Rebellion will soon give place to men for whom the war is a remembrance simply and not an actual experience.

MEDICAL NOTES.

APPOINTMENT OF PROFESSOR OSLER. — It is announced that Dr. William Osler has been appointed Regius Professor of Medicine at Oxford University, succeeding Sir John Burden-Sanderson.

IMMIGRATION RULES. — Among other immigration rules about to be established, the following is of interest to the medical profession, that a law be enacted regarding medical inspection of the immigrants at points of embarkation for this country. It appears that during this past year several hundred immigrants, suffering from dangerous communicable disease, have been deported at the expense of transportation companies. Could a more stringent examination be made of persons before embarking, an element of danger and also a source of great inconvenience would be removed.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon Aug. 17, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diptheria 35, scarlatina 7, typhoid fever 30, measles 8, smallpox 0.

BEQUESTS. — By the will of the late Miss Mary McGregor Means the sum of $3,000 is bequeathed to the T. Morgan Rotch, Jr., Hospital of Boston, and $2,000 to the House of the Good Samaritan. Anonymous gifts of $800 have also recently been given to the Boston Floating Hospital.

CONTAMINATION OF THE NEPONSET RIVER. — In accordance with an act of the Legislature in 1902, prohibiting the entrance or discharge of sewage into the Neponset River or its tributaries, and also of other substances injurious to public health, unless such substances be rendered harmless, the Massachusetts State Board of Health has taken action. Last summer the Board called the attention of property owners to the matter, to which it is said the latter have paid small attention. As a result, the Board now calls upon the attorney-general for an enforcement of its decree. Plants valued at from fifteen million to eighteen million dollars are affected by the order, but the manufacturers have never been willing to admit the right of prohibition of drainage into the river. It is, therefore, regarded as possible that the action of the Board may still be contested, although both law and right seem to be on the side of the complainants.

BACTERIOLOGICAL LABORATORY OF BOSTON BOARD OF HEALTH. — The Bacteriological Laboratory of the Boston Board of Health is soon to be transferred from its old outgrown quarters in the Sudbury Building, occupied since 1898, to the Boylston Chambers, 739 Boylston Street, where greater space and convenience have been secured. The existing arrangements for the free delivery daily up to 6 P.M. of cultures, through culture stations, will be continued exactly as heretofore. An addition to this has now been made, in that hereafter cultures too late for this free delivery may be sent for incubation, direct to the laboratory up to 9 P.M. The expense of delivering such late cultures will, however, rest with the physician, not with the culture stations. In addition to the diagnostic work, which has increased very much since the laboratory was established, the bacteriological examination of the Boston milk supply was begun in June, involving the examination of about six hundred samples each month.

NEW YORK.

MUZZLING OF DOGS. — On Aug. 10 State Commissioner of Agriculture Weiting issued an order, directing that in the city of Binghamton and in certain districts of Tioga, as well as Broome

County, all dogs should at once be muzzled or killed. A short time previously a rabid dog came to Binghamton from Oswego and is known to have bitten over fifty animals, some of which have since developed rabies.

Gift to Medical Department, Tulane University. — By the will of the late Alexander C. Hutchinson the bulk of his property, partly in New York and partly in New Orleans, is bequeathed to the medical department of Tulane University, Louisiana. The appraisement, just filed in the surrogate's office, New York, shows that the testator left a personal estate amounting to $1,020,000, in addition to considerable real estate, the value of which is not made public.

Accident to a Summer Tuberculosis Camp. — On August 10, what is described as a veritable whirlwind, came up from the sea at Coney Island and demolished the tents of the camp instituted this summer by the Association for Improving the Condition of the Poor, for children suffering from tuberculosis of the bones and joints. The frightened children were drenched by the rain which accompanied the wind, but the nurses soon had them housed in the neighboring building of the society.

Bequests. — Among other charitable bequests left by the will of the late Marcus Goldman of New York are $1,000 each to the Mount Sinai Hospital and the Montefiore Home and Hospital for Chronic Invalids. By the will of Simon Lavenburg of New York, who died recently in Germany, most of his estate is left to charity, on the death of his widow. Among the bequests are $5,000 each to the Mount Sinai Hospital and the Montefiore Home and Hospital for Chronic Invalids.

Quarterly Mortality Statistics. — The condensed quarterly report of the Bureau of Records of the Health Department, just issued, which embraces the three months ending March 31, 1904, shows that the number of deaths for the quarter was 21,590. This, on an estimated population of 3,838,024, gave a death-rate of 22.58 per thousand, as compared with the average number of deaths for the preceding five years of 18,301, which, on an estimated population of 3,540,664, gave a death-rate of 20.98 per thousand, an increase of 1.60 points. The reason for this increased death-rate, as compared with the quinquennial average, is given as due to three factors, namely: First, an immense increase in the prevalence of measles; second, a persistent and severe type of influenza; and third, the unusually severe winter. The first of these factors, measles, was the forerunner of an increase in the number of deaths from respiratory diseases among children, while the second and third factors contributed to the increase in the respiratory, circulatory, urinary and tubercular diseases among adults and old people. The increase of deaths from pneumonia was 1,437 above the quinquennial average. The increase in the number of deaths under five years of age was 546, at the ages five to sixty-five years, 2,177, and at sixty-five years and over, 546 above the quinquennial average.

Obituaries.

JOSEPH WIENER, M.D.

Dr. Joseph Wiener, an eminent retired New York physician, died from cardiac disease on Aug. 11, in the seventy-seventh year of his age. He was born in Hanska, Bohemia, April 5, 1829, and came to this country in 1849. For thirty-five years he was in active practice in New York, and during a considerable part of this time was an associate of the late Dr. William Detwold in the chair of military surgery at the College of Physicians and Surgeons, since affiliated with Columbia University. He was also one of the founders of the department of pathology in that school. Dr. Wiener was prominent in literary and artistic circles, as well as identified with many philanthropic and scientific movements. In 1885 he made the presentation speech on the occasion of the unveiling of the bust of Washington Irving in Bryant Park, New York.

WENDELL C. BOYD, M.D.

Dr. Wendell C. Boyd died at Linneus, Me., Aug. 3, 1904, aged thirty-four years and two months. The deceased was born at Linneus, received his early education in the district schools of his native town and at the Ricker Classical Institute of Houlton, Me., of which he was a graduate. He took his medical degree at the Harvard Medical School in the class of 1893, and at once entered into practice with his father, Dr. Robert Boyd, quickly meeting with success. He possessed a large fund of personal magnetism and professional tact which made his presence acceptable in the sick room, and in his early demise he leaves a great number of friends. He was twice elected and served two terms in the Maine legislature.

About one and one-half years ago he suffered from a severe attack of influenza from which he never fully recovered. Soon pulmonary tuberculosis developed, and after a vigorous fight of over a year his death quietly came.

The esteem in which he was held was attested by the large concourse of people who came to pay tribute to him in death. He leaves a wife

and one child, aged four years. His parents also survive him, with one brother (present Secretary of State of Maine) and one sister, the wife of Dr. W. N. Hand of Woodstock, N. B.

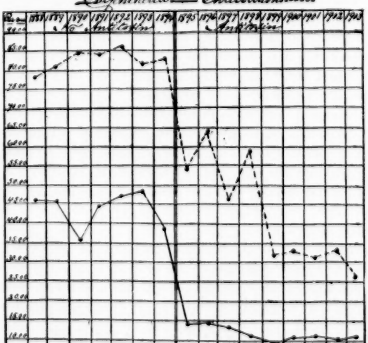
Miscellany.

DIPHTHERIA STATISTICS AT THE BOSTON CITY HOSPITAL.

The following figures show the number of cases of diphtheria treated at the Boston City Hospital, proper, and at the South Department from 1888 to 1903, inclusive. The number of cases of intubation for the same time is also shown. 1888 to 1894, no antitoxin. 1895 to 1903, antitoxin.

Year.	Number of Cases of Diphtheria.	Died.	Per cent. of Mortality.	Per cent. of Recoveries.	Number of Intubations.	Died.	Per cent. of Mortality.	Per cent. of Recoveries.
1888	382	176	46.07	53.92	100	78	78.00	22.00
1889	529	239	45.17	54.82	128	104	81.25	18.75
1890	415	151	36.38	63.61	93	79	84.94	15.05
1891	237	105	44.30	55.69	50	42	84.00	16.00
1892	387	185	47.80	52.19	65	56	86.15	13.84
1893	419	203	48.44	51.55	109	90	82.56	17.43
1894	698	266	38.10	61.89	89	74	83.14	16.85
Total,	3067	1325	43.20	56.79	634	523	82.49	17.50
1895	1455	207	14.22	85.77	118	64	54.23	45.76
1896	1889	276	14.61	85.38	224	145	64.73	35.26
1897	1387	181	13.04	86.95	146	67	45.88	54.11
1898	817	97	11.87	88.12	71	42	59.15	40.84
1899	1621	162	9.99	90.00	192	63	32.81	67.18
1900	2547	293	11.50	88.49	259	87	33.59	66.40
1901	1576	185	11.73	88.26	184	58	31.52	68.47
1902	1008	111	10.20	89.79	145	49	33.79	66.20
1903	1179	138	11.70	88.29	139	37	26.61	73.38
Total,	13479	1650	12.24	87.75	1478	612	41.40	58.59

Percent of Mortality of Diphtheria at the Boston City Hospital, proper, and at the South Department from 1888 to 1903 inclusive. Percent of Mortality of Intubations for the same time. 1888 to 1894 No Antitoxin. 1895 to 1903 Antitoxin. Diphtheria. Intubations.



Correspondence.

MEDICAL EXHIBITS AT THE WORLD'S FAIR.

St. Louis, Aug 15, 1904.

To the physician anticipating a visit to the World's Fair, mention of the various medical exhibits to be seen, both foreign and domestic, will not be out of place; and to his less fortunate brother a description of some of these will be of interest.

The medical exhibits, with the exception of those of the Marine Hospital Service, and the Medical Department of the Army and Navy, in the Government Building, are all in the Educational Building, arranged under the head of their respective states or nations. While all these exhibits are interesting and instructive, Germany, in the variety and scope of her exhibit, and the general excellence of its character, both in regard to the material displayed, and also as illustrative of the method of medical instruction, should certainly be given first place.

There are eight sections devoted to the medical sciences in the German exhibit alone. The first section, taking them in order, displays a heterogeneous collection, consisting chiefly of models and instruments, for the purpose of medical instruction. On entering the door, the first thing one notices is a case of instruments from the firm of Louis & H. Lowenstein of Berlin. Among these instruments may be mentioned Prof. Nitze's cystoscopic instruments, and a rubber phantom of the bladder by means of which the technic of cystoscopic instrumentation is taught the student. One other instrument should be mentioned, and that is an esophagoscope by Gluckmann, which is considered by the Germans to be superior to that devised by Mikulicz and Gottstein. Close by are phantoms for the purpose of passing the esophagoscope and for practising instrumentation by the aid of the laryngeal mirror. From the manufactories of Carl Zeiss, are some very beautiful optical instruments consisting of microscopes, dissecting microscopes, photomicroscopes and the various accessories.

The method of instructing the student in anatomy, the various steps of surgical operations, and the external appearance of disease is well shown by means of wax models. From Professor Passow's otological clinic at the Charité Hospital, Berlin, are models illustrative of the typical ear operations, the steps of a mastoid operation being especially well explained. A wax model for the purpose of explaining the manner of opening the frontal sinus is here displayed; also a model used in lecturing on the nose and accessory sinuses. The anatomical display consists of a complete dissection of the foot, showing the relations of muscles, tendons and ligaments, and a collection of tarsal bones.

From the studio of Fritz Kolbow of Berlin may be seen some very beautiful preparations in wax of tuberculosis and carcinoma about the face; also affections of the eye, such as tracoma, diphtheritic conjunctivitis, and gonorrheal ophthalmia. These preparations are so perfect that those not in the profession at first sight ask if they are not specimens preserved from the human body. On the wall of this room are many pictures taken at the Orthopedic Clinic at Berlin showing the effect of the subcutaneous injection of hard paraffin in plastic surgery with the most pleasing result. Pictures from the Medico-Legal Institute of the Royal University of Berlin show many of the conditions met with when death from violence occurs.

Passing on to the next section, one enters the x-ray and lecture rooms where exhibitions of the Roentgen rays are given. The next six sections contain the main exhibition of the medical department, each section representing one branch of the medical sciences. The first of these six sections is arranged by the Imperial Board of Health of Berlin and the Royal Ministry for Medical Affairs to illustrate the method of combating epidemics, bacteriological research, and experimental therapeutics. This room is fitted up as a bacteriological laboratory and displays the latest and most approved forms of apparatus for bacteriological research, also a compact "flying laboratory" which can be quickly and easily moved from

place to place, and contains everything necessary for the purpose of investigating epidemics. On the wall of the room are pictures of patients afflicted with smallpox, leprosy and bubonic plague. The exhibition of this latter disease deserves special mention on account of its completeness and excellence. In addition to the pictures showing the different stages of the disease, are pictures of the pathological anatomy of different organs infected; also pictures of the wards and laboratories where the investigations are carried out. On a table beneath is a model of the apparatus used for killing rats on board vessels, a preventive against the importation of plague. The agent used for this purpose is carbonic acid gas which is introduced into the vessel through the air shafts, the rest of the openings having been sealed up. Cultures of the plague bacillus, pathological specimens of different organs infected, and rats inoculated and preserved in Kaiserling fluid show beautifully the character of this disease.

Plates and cultures, showing the growth of different organisms, may be seen here. They include not only the ordinary pyogenic organisms, but those producing anthrax, meningitis, pneumonia, influenza, glanders, actinomycosis, Asiatic cholera, tetanus, diphtheria, dysentery, typhoid and tuberculosis. Among the therapeutic agents displayed are antitoxins for combating certain of these diseases; as diphtheria, tetanus, anthrax and swine erysipelas. The inoculating agent and the apparatus and methods of inoculating and obtaining the serum are here shown. The exhibition of the pathology of typhoid, diphtheria, and Asiatic cholera, is very good, showing in each case the culture of the organism producing the disease and the lesion in the infected organs. Monographs on the nature of the infectious diseases are placed with the corresponding exhibits for distribution to and instruction of the public in the cause, character and means of preventing these diseases.

In the next room devoted to anatomy are some very beautiful dissections of the muscles of the upper extremity preserved in Kaiserling fluid. A series of dissections of the foot showing the muscles, tendons, nerves, blood vessels and ligaments; a dissection of the brain showing in detail its gross anatomy; a series of twenty-two cross sections of the human head, neck and shoulders, illustrating this method of study and instruction, are here displayed. Sections of the temporal bone to show the minute anatomy of the ear are not the least important of this exhibit.

A number of wax models of the various joints and ligaments, a model of the human fetus, and a very interesting model of the development of the urogenital apparatus, are arranged by Dr. Boesike, prosector at the Anatomical Institute of Berlin. A refutation of the idea of maternal impressions is seen in the display of sixteen specimens of malformations in birds and mammals produced experimentally.

The surgical exhibit is arranged in two sections; one representing the Royal Surgical clinic of Berlin; the other the Royal Surgical clinic of Breslau. The first room shows the exhibits from the Royal Surgical clinic of Berlin under the direction of Prof. Dr. von Bergmann and contains many interesting models in wax of surgical procedures, such as, the extirpation of the tongue after dividing the ramus of the jaw, extirpation of the larynx, and hemicraniotomy. These models are very beautifully made and show in detail the various steps of these operations, and the anatomical relations. The successive steps of the Bassini operation for the radical cure of inguinal hernia are very clearly pictured by these models, also Von Bergmann's operation for making a gastric fistula. In addition there are pictures of tumors about the head, face and neck, showing by comparison the difference in appearance of the various growths that may occur in those regions. A number of very fine specimens of sarcoma preserved in Kaiserling fluid may be seen here.

The next section contains the exhibit of the Royal University of Breslau, under the direction of Prof. Dr. von Mikulicz-Radecki. Here may be seen, arranged around the walls of the room, an exhibit of the surgical affections of the knee, illustrated by casts taken from the living, and produced in wax, showing the difference in appearance of sarcoma, tuberculosis, tabetic arthropathies, loose bodies in the joint, effusions into the knee, and fractured patellæ — a comparison of the normal and affected knee being shown in each case.

On the stand beneath are prints taken from the original Roentgen-ray plates, and schematic drawings traced from the same plates to show the character of the growth in these different affections. On an adjacent stand are wax models illustrating the technic of certain abdominal operations. Among these may be mentioned the various skin incisions most commonly practised in abdominal operations at the clinic of Von Mikulicz; a model showing the important points in a posterior retrocolic gastro-enterostomy and a resection of the pylorus with an end-to-end anastomosis by means of a Murphy button. Near by may be seen a demonstration of esophagoscopy by means of a phantom showing the esophagoscope in position with a revolving disc at the distal end holding wax models of the pathological conditions which may arise in the living. There are photographs of foreign bodies lodged in the esophagus, and x-ray photographs — some negative, some positive. The diagnosis in each case was made by means of the esophagoscope, and the foreign body removed through the mouth, or pushed into the stomach and passed per rectum. Other cases are shown in which the diagnosis having been made by the esophagoscope esophagotomy became necessary to dislodge the foreign substance. Some very fine wax models from the dermatological clinic of Breslau and a display of surgical instruments and apparatus from the firm of Georg Haertel of Breslau completes this section.

Adjoining the surgical section is a room for the display of the pathological exhibit. Here wax models for the demonstration of an autopsy are shown. The thoracic cavity is exposed and the heart is grasped by a hand to show its position when opening the right and left side of the heart.

Wax models of the brain are displayed, explaining Virchow's method and the position of the hand in cutting the brain. These models are very beautiful and show perfectly the section of the brain, the cerebral hemispheres, basal ganglia, and cerebellum. The pathological specimens are extremely interesting and well preserved, Kaiserling fluid being the preservative most commonly used. The exhibit of sarcomatous tissue is especially fine; one display shows the secondary deposits which have taken place in the mesentery, liver and vertebral column; another shows the dissemination of a melanotic sarcoma, arising from a pigmented mole, involving the uterus, intestines, peritoneum, liver, lung and brain. The pathological conditions of the kidney are well illustrated. There are some excellent specimens of renal calculi, renal cysts, a specimen showing a compensatory hypertrophy of the right kidney with atrophy of the left, amyloid degeneration of the kidney, and last and very interesting is a specimen of tuberculous urethritis, cystitis, ureteritis and nephritis showing a caseous ulcerating condition of one kidney and a cyanotic induration of the other. A very fine specimen showing the effect of an unchecked hemorrhage of the dura is to be seen here, the dura with the clot is removed showing the resulting compression of the brain. A series of sections of the bones is displayed to show the pathology of rachitis, and several skeletons show the osseous deformities seen in the bones of the thorax.

The final section of this exhibit is devoted to internal medicine. As this subject is hard to picture, since the means of study, the manner of making a diagnosis and the method of treatment are taught mainly by lectures, it was decided to take as an example one disease, namely, tuberculosis. Through the assistance of the makers of diagnostic instruments, manufacturers of hospital supplies and accessories, and the pathologist, the means of making a diagnosis, the manner of prevention and the method of treatment of this disease are explained.

Here are also shown various forms of microscopes, stethescopes and laryngoscopes, apparatus for sterilizing clothing and rooms, and receptacles for the sputum. A model ward tent and a bed which can be utilized as a chair or bed illustrate a feature in the open air treatment of this disease. The pathology of the disease is pictured by specimens of the various organs involved.

This completes one of the most remarkable and thoroughly representative exhibitions of the Fair, embracing as it does almost every department of the medical sciences.

Deaths reported, 3,484; under five years of age, 1,457; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,333; acute lung diseases 204, consumption 350, scarlet fever 9, whooping cough 15, cerebrospinal meningitis 27, smallpox 1, erysipelas 4, puerperal fever 4, measles 10, typhoid fever 50, diarrheal diseases 815, diphtheria and croup 48.

From whooping cough, New York 2, Chicago 6, Philadelphia 1, Pittsburg 6. From measles, New York 6, Philadelphia 2, Pittsburg 1, Boston 1. From scarlet fever, New York 2, Chicago 3, Philadelphia 3, Baltimore 1. From cerebrospinal meningitis, New York 18, Baltimore 2, Pittsburg 1, Boston 4, Worcester 1, Pittsfield 1. From typhoid fever, New York 13, Chicago 7, Philadelphia 5, Baltimore 3, Pittsburg 15, Boston 5, Fall River 1, Lynn 1. From erysipelas, New York 1, Chicago 2, Lawrence 1. From small-pox, North Adams 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending July 23, the death-rate was 14.1. Deaths reported 4,142; acute diseases of the respiratory organs (London) 36, whooping cough 91, diphtheria 50, measles 177, smallpox 5, scarlet fever 24.

The death-rate ranged from 3.1 in West Bromwick to 20.3 in Liverpool; London 14.8, West Ham 14.1, Brighton 13.6, Southampton 13.9, Plymouth 13.3, Bristol 11.5, Leicester 9.5, Nottingham 14.5, Bolton 15.4, Manchester 14.6, Salford 17.8, Bradford 16.8, Leeds 16.6, Hull 13.1, Sheffield 11.7, Cardiff 10.6, Rhondda 19.6, Wigan 10.0, Merthyr Tydfil 16.5, Bournemouth 9.7, Bootle 18.6.

METEOROLOGICAL RECORD.

For the week ending August 6, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING AUGUST 13, 1904.

W. N. MCDONNELL, acting assistant surgeon. Detached from the "Marcellus" and ordered to the Naval Recruiting Rendezvous, Baltimore, Md.

V. DABNEY, acting assistant surgeon. Detached from the Naval Recruiting Party No. 3, and ordered home to wait orders.

R. C. DEAN, medical director. Detached from duty as a member of the naval retiring board, Washington, D.C., and ordered home.

G. F. DUNCAN, acting assistant surgeon. Detached from the Naval Recruiting Party No. 2, and ordered to the "Franklin."

W. H. JANNEY, acting assistant surgeon. Detached from the Naval Recruiting Party No. 1, and ordered to the "Marcellus."

G. A. LUNG, surgeon. Detached from the "Hancock" and ordered to the "Kentucky."

M. S. GUEST, passed assistant surgeon. Detached from the "Kentucky" and ordered to Washington, D. C., September 1, for examination for promotion and to wait orders.

F. A. ASSERSON, assistant surgeon. Detached from the "Kentucky" and ordered home to wait orders.

P. T. DESSEZ, assistant surgeon. Detached from the Naval Academy and ordered to the "Kentucky."

APPOINTMENTS.

The New York School of Clinical Medicine announces the following changes in the faculty: General Medicine: Professors Wm. Brewster Clark and Henry Lawrence Schively; Associate Professors Thos. M. Acken and Edw. L. Kellogg; General Surgery: Prof. Simon J. Walsh and Assoc. Prof. J. Cameron Anderson; Gynecology: Professors Augustin H. Goelet and A. Ernest Gallant; Pediatrics: Professors Dillon Brown and Henry Comstock Hazen; Nervous and Mental Diseases: Professors J. Arthur Booth and Emmet C. Dent; Gastro-Intestinal Diseases: Prof. Robert Coleman Kemp; Ophthalmology and Otology: Professors John L. Adams and Geo. Ash Taylor; Dermatology: Prof. Robert J. Devlin; Laryngology and Rhinology: Prof. Max J. Schwerd; Orthopedic Surgery: Prof. Homer Gibney; Hydrotherapeutics: Prof. Alfred W. Gardiner; Genito-Urinary Diseases: Professors Wm. K. Otis, Walter Brooks Brouner and John von Glahn; Pathology: Prof. E. E. Smith.

RECENT DEATH.

ALBERT W. WARDEN, M.D., of Union Hill, Hudson Co., N. J., died at the Presbyterian Hospital, New York, on August 9, of septicemia, resulting from a poisoned wound received while attending a patient. Dr. Warden, who was forty-seven years of age, organized the first free public library at Union Hill, where he also served as a school trustee.

BOOKS AND PAMPHLETS RECEIVED.

American Edition of Nothnagel's Practice. Tuberculosis and Acute General Miliary Tuberculosis. By Prof. Dr. G. Cornet. Edited, with additions, by Walter B. James, M.D. Authorized translation from the German, under the editorial supervision of Alfred Stengel, M.D. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

Original Articles.

THE PRESENT STATUS OF HYDROTHERAPY AND OTHER FORMS OF PHYSICAL THERAPEUTICS.*

BY JOSEPH H. PRATT, A.M., M.D., BOSTON,
Physician to Out Patients, Massachusetts General Hospital; Assistant in the Theory and Practice of Physic in Harvard University

IN an admirable address delivered at the opening of the balneological course at Baden-Baden last October, Professor Vierordt [1] asserted that the recent introduction of physical methods of treatment marked a turning point of great importance in the history of medicine. In the past, the reluctance of scientific physicians to avail themselves of physical agents — light, water, air, heat, electricity, movement — has been in large part due to the fact that their use did not rest upon a scientific basis. They were employed chiefly by men devoid of scientific accuracy, untrained in careful diagnosis, who, content to allow physical methods to be judged by results obtained, made extravagant claims for them and introduced, to explain their use, wild conjectures and theories unsupported by physiological and pathological evidence. Within the past decade, however, empiricism in physical therapeutics has been overthrown, and to-day the use of air, water, heat and other natural methods of cure rests upon a firm foundation.

It is not surprising that the study of gross and microscopical morbid anatomy caused a loss of therapeutic faith, amounting in many instances to a denial of the efficacy of almost all medicines. The futility of the treatment employed was too often apparent at the postmortem table. This spirit of therapeutic hopelessness is passing away. A knowledge of pathology no longer presupposes that its possessor has no interest or faith in treatment. It is true that faith in drug therapy has not increased, but the value of physiological procedures is realized more and more as knowledge of physiological and pathological processes increases and nature's modes of cure are better understood. Let me cite an illustration. The tubercle bacillus is ubiquitous, and the only reason any individual escapes infection is owing to the ability of the healthy tissues to destroy the bacilli, and the only method of cure is to increase the resistance of the tissues. Judged by a study of morbid anatomy alone, few diseases would seem more hopeless than phthisis pulmonalis. Yet everyone knows that fresh air, good food and rest cure more than half of the incipient cases, and diminish or remove the distressing symptoms from those in whom the disease is far advanced.

The interest and study given to the investigation of physical therapeutics by the leaders of medical thought in Germany is certainly a hopeful sign. This new movement has resulted in the development of a system which embraces within its scope the treatment of all forms of disease. There is no attempt to substitute physical procedures for drugs of recognized value, but to combine both methods of treatment.

The experimental method in the study of hydrotherapy was introduced by Winternitz over thirty years ago, and his treatise published in 1877 placed hydrotherapy on a physiological basis. Although it was one of the first physical methods to be granted a place in scientific medicine, knowledge of the mode of action of water upon metabolism, the circulation, the blood and the nervous system is still very imperfect. The work which was begun along proper lines by Winternitz is now being extended, and during the past year important researches upon subjects connected with hydrotherapy have been reported in some of the leading scientific journals of Germany, — *Deutsches Archiv fur klinische Medizin, Zeitschrift fur klinische Medizin, Ziegler's Beitrage, et al.*

The reason that physiological therapy has developed so rapidly in Germany is explained by the fact that its study has been undertaken with the same thoroughness and by the employment of the same critical methods and with the same scientific spirit as has characterized the work of the Germans in physiology, pathology and the other fundamental medical sciences.

Of all the non-medicinal methods of treatment, nutrition therapy, to use a term introduced by von Leyden, has reached the highest point of development. It is the knowledge of the physiology of nutrition gained by the investigations of Justus von Liebig, Voit, Rubner, and others, which gives dietetics the important place it now holds.

The beginnings of this new period in therapeutics date back many years. Early in the last century a method of medical gymnastics was introduced by Ling in Sweden which is used to-day. Within comparatively recent times, Gustav Zander, another Swede, devised a system of mechanical gymnastics, and invented elaborate and ingenious apparatus. The Frenchmen, Junod, Tabarié and Pravaz, laid the foundation of pneumotherapy. Electrotherapy originated with Duchenne, of Boulogne, and its scope was extended by Erb, of Leipsic, now of Heidelberg. The recently developed light therapy is chiefly due to the investigations of Finsen, of Copenhagen. The compensatory exercise-therapy, so valuable in the treatment of tabes dorsalis, was introduced by the Swiss physician, Frenkel. Local hot air baths for arthritis were first employed by Bier, while an assistant of von Esmarch at Kiel. Scientific hydrotherapy, as we have said, is chiefly indebted to the Austrian, Winternitz. Thus it will be seen that modern physical therapeutics was developed by many men in different countries. These pioneers, isolated from one another, worked along special lines, and until recently their influence on medical practice was not great.

Some of the leaders of medicine, among whom was the honored Kussmaul, saw with almost prophetic vision the direction in which the therapeutics of the future would progress, and realized

* Read before The Massachusetts Medical Society, June 8, 1904.
[1] Vierordt. Die Therapie der Gegenwart, Nov., 1903.

the need of instructing the physicians and students of their generation in dietetics and methods of physical treatment. Eulenberg and Samuel, in their Handbook, pointed out clearly this defect in medical education, which existed in Germany as late as 1898. Much has been accomplished within the past ten years, and for this rapid development great credit should be given to Professor von Leyden, who has utilized the commanding position he holds in German medicine to the advancement of physical therapeutics. In 1897 he published, with the collaboration of the leading authorities, the "*Handbuch der Ernahrungstherapie*" in two large octavo volumes. This was so successful that another edition has been prepared, the second volume of which has just been issued. V. Leyden also established a journal, devoted exclusively to dietetics and physical therapy — the *Zeitschrift fur diatetische und physikalische Therapie*.

Inspired by von Leyden, his associate, Goldscheider, and assistant, Jacob, issued the "*Handbuch der physikalischen Therapie*," in four volumes — an admirable work to which Hoffa, Eichhorst, Jolly, v. Liebermeister, Litten, Nothnagel, Riegel, Senator, and other well-known university teachers, contributed.

At the present time, in Germany, the leaders in internal medicine are the leaders in physiological therapeutics. Nothing indicates more clearly the present status of hydrotherapy in Germany than the fact that the three largest university clinics have recently been equipped with the latest and most approved apparatus for water treatments.

In Berlin, the University maintains a hydrotherapeutic institute at the Charité. It was opened in January, 1901, and is under the direction of Professor Brieger, distinguished for his investigations in chemistry and bacteriology. In establishing the institute, Brieger was aided by Professor Koch, a verification of the statement I have made that this new development in therapeutics appeals to the scientific mind.

Up to April, 1903, about 34,000 treatments had been given in Brieger's hydrotherapeutic polyclinic, important researches made, and nearly twenty-five papers published.[2] His lectures on general therapeutics were attended by one hundred and forty-five students, and three hundred and fifty-four physicians received instruction. Light, heated air, massage and mechanotherapeutic procedures are used in conjunction with hydrotherapeutic measures.

In connection with v. Leyden's medical clinic, is a department for physical therapeutics under the immediate charge of Paul Jacob, whose interesting report of the work accomplished during the past year occupies thirty-five pages of the latest volume of the *Charite-Annalen*.

The *Anstalt* for physiological therapeutics in the University Clinic at Munich is one of the most complete in the world. It was equipped by the Bavarian government at great expense. The hydrotherapeutic arrangements are unexcelled. There are facilities for full baths, half baths, local baths (arm, foot, etc.), sitz-baths combined with douches for the back, abdomen or vagina, vapor baths and vapor douches, hot-air baths, sand baths, mud baths, fango packs, salt baths, carbon dioxide baths, sulphur baths, electric baths and a variety of douches.

Several small rooms are devoted to inhalation therapy. One sees here the remarkable inhalatorium devised by Wassmuth, and other simpler systems of inhalation are also to be found. A large hall is devoted to mechanotherapy, and contains twenty-two different forms of Zander's apparatus for passive and resistant movements and massage manipulations. Another room contains a Finsen light of the original pattern, and general and local electric light baths.

The great Leipsic clinic is well fitted up with appliances for hydrotherapeutic treatments, as is also Erb's clinic at Heidelberg.

Many years ago, Liebermeister built rooms in his Tübingen clinic for hot air and vapor baths. At the present time, the hot air cabinet is generally preferred to the hot chamber (Turkish bath), because in the former the patient is not compelled to breathe super-heated air, and danger from congestion of the lungs is averted. Moreover, it is easier to supply pure air and the temperature of the bath can be regulated to the needs of the individual.

Elaborate apparatus is not essential to success in hydrotherapy. Much can be accomplished, as someone has said, with a bucket of water and and a couple of towels, if intelligently applied. For over fifteen years, simple hydrotherapeutic procedures have been extensively used in Professor Stintzing's clinic at Jena, in the treatment of chronic as well as of acute disease, including severe organic maladies. That the measures employed have yielded important results is indicated by the publication of Matthes' text-book of clinical hydrotherapy, based in part upon the experiences of the Jena clinic where Matthes served as assistant for nearly ten years. This work is probably the best, as well as the most scientific that has appeared. The opinions expressed are conservative and convincing. The author is not simply a specialist in hydrotherapy, but is a professor in the university, director of the medical polyclinic at Jena, and recognized as among the ablest of the younger German clinicians.

Another indication of the important place hydrotherapy holds in German medicine of the twentieth century is the attention given to this subject in the latest standard works on internal medicine. In the last edition of v. Strümpell's "*Lehrbuch*," water treatments are recommended in sixteen diseases, exclusive of those of the nervous system. In Penzolt and Stintzing's "*Handbuch der Therapie innerer Krankheiten*," third edition, 1903, over one hundred and fifty pages are devoted to the general hydrotherapy and balneotherapy of diseases of the nervous system.

In the summer semester of 1902, the following German universities offered one or more courses

[2] Krebs. Die medicinische Woche, 1903, iv, p. 255.

in some department of physical therapeutics, usually hydrotherapy: Berlin, Bonn, Breslau, Erlangen, Greifswald, Halle, Heidelberg, Leipsic, Munich, Strassburg, Tübingen, Rostock and Würzburg. This makes a total of thirteen out of the nineteen universities which gave specials on these subjects in a single half year. Compare this record with that of our American university schools, none of which, so far as I have been able to learn, gives a similar course.

In addition to the opportunities for instruction in the physical therapy of medical diseases, Ritter, of Bier's clinic, devoted a course to physical methods in surgery. During the present semester, one of the two courses given by Proffessor von Strümpell, at Breslau, is limited to physical therapeutics.

Austria is the home of modern hydrotherapy. At Kaltenleutgeben, in 1862, Wilhelm Winternitz, the "father of scientific hydrotherapy," established his sanitarium for water treatments, which has increased from eighteen patients treated the opening year, to two thousand patients in 1896. Winternitz founded at his own expense an out-patient hydrotherapeutic clinic, in connection with the university hospital at Vienna. Later he was made *ausserordentlicher* professor of internal medicine. He has given instruction in hydrotherapy to hundreds of physicians. In 1890, he founded the *Blatter fur klinische Hydrotherapie*. This has become the standard journal of hydrotherapy, and its original articles and reviews record nearly all the advances in this department of medicine.

In the model clinic of Jaksch Ritter von Wartenhorst, at Prague, are appliances for the most approved hydrotherapeutic treatments, and in the curriculum of 1904 he included, as is his custom, a two-hours' weekly course on hydrotherapy. Professor Pribram, in the same university, also offers special instruction in physical therapeutics.

At the *Spedale S. Maria nuova*, in Florence, connected with Grocco's medical clinic, is an institute for physical therapeutics which compares favorably with any in the world. According to Baruch, it possessed in 1900 the best douche apparatus in Europe. At the time of my visit, two years later, the establishment was supplied with the latest appliances for other forms of physical therapy. It was interesting and significant to note that the equipment was of Italian manufacture.

In Rome, an institute devoted to physical therapy has recently been opened which is complete in its appointments. The architect of the palatial building, with a true artistic sentiment, caught the spirit of the movement, and the classic style adopted not only gives the institute the character of a public building, but permits the entrance of the largest possible amount of sunlight. The director, Professor Colombo, holds an academic position in the University of Rome and is the editor of the *Revue Internationale de Therapie Physique*.

Practical hydrotherapy developed more rapidly in France than in any other country, and has for many years been held in high repute by leading clinicians. Fleury, a member of the faculty of medicine of Paris, introduced the douche, which is the most valuable of all hydriatic procedures in chronic disease. His excellent "*Traite d'hydrotherapie*" reached its fourth edition as early as 1875. Charcot used hydrotherapeutic measures constantly in his practice. Probably the best presentation of the douche treatment, which is known as the French method, is to be found in the manual of Beni-Barde and Materne, published in Paris in 1894.

In England, hydrotherapy has scarcely gained a foothold. Dr. Calvert, warden of St. Bartholomew's Hospital, told me he knew of no institution that had any special equipment for this form of treatment. The facilities for light therapy, however, at the London Hospital are admirable. Three of the original Finsen arc-lights have been installed, and a number of small lights of the French pattern. This movement was inaugurated by Queen Alexandra. Over a hundred cases of lupus receive daily treatment. The Röntgen rays and Tesla coil are also used.

Even hydrotherapy, in acute diseases, has made little progress in Great Britain, although it was early advocated by Wilson Fox and Ord. The leading champion of the cold bath treatment in typhoid fever has been Cayley, who, in the Croonian lectures for 1880, clearly and convincingly set forth its advantages.

Strange it is that the land of Currie, whose teachings influenced Brand, should be the last to adopt the cold water treatment in typhoid fever. There is some evidence, however, that the clouds of prejudice are being swept away. In the typhoid fever number of the *Practitioner*, published in January, 1904, Dr. J. W. Moore, in discussing the treatment, says that "in the water treatment alone have we a safe and certain means of controlling, or even reducing, temperature in the febrile state," and in another paper, contributed to the same journal, Dr. Hawkins states that for "controlling pyrexia there is nothing like cold water."

Mention should be made of the excellent *Journal of Balneology and Climatology* published in England, to which the distinguished clinical physiologist, Oliver, has contributed valuable articles.

The modern cold bath treatment of typhoid fever was introduced into America and first systematically used by a Fellow of this Society, Dr. R. T. Edes, who honors us with his presence to-day. In 1875, he presented at this annual meeting an able and scholarly paper, characterized by its philosophical tone, in which he described the work of Brand, Ziemssen and Liebermeister, and reported that he had used the graduated cold full bath with friction since 1872 in sixty-six cases of typhoid fever. Of thirty-two patients treated from the first week of the disease, only one died. The pity of it is that the generation to whom he announced this was so blinded that it could not see the truth. Think of the

lives needlessly sacrificed in Massachusetts alone since 1875, because Dr. Edes' advice was not heeded, — not the old and decrepit, but those in the vigor of early adult life. The cold full bath is certainly a heroic method, but it should be used because it saves life. Since July, 1890, hydrotherapy in typhoid fever has been practised by Dr. Osler at the Johns Hopkins Hospital, with a reduction in the death-rate to seven and a half per cent. Equally good results have been obtained by Gilman Thompson in New York and J. C. Wilson and Tyson in Philadelphia.

In this country, the value of hydrotherapy in chronic diseases has been specially emphasized by Kellogg and Baruch, and it has been used by Dr. J. J. Putnam for over twenty years.

The first modern work in the English language dealing with hydrotherapy and untainted with quackery was Winternitz's monograph in Ziemssen's "Handbook of Therapeutics," which was translated from the German in 1884. In 1892, Dr. Baruch published a short but excellent work on the "Uses of Water in Modern Medicine." Later his larger treatise on hydrotherapy appeared. Recently the second edition was issued, which shows not only that the book has been well received, but indicates an increasing interest in hydrotherapy among physicians.

Kellogg's "Rational Hydrotherapy" appeared in 1900. Although a large and expensive work, it has already reached a second edition. It is most comprehensive, and its descriptions of technic are worthy of special commendation.

A system of physiological therapeutics, in eleven volumes, edited by Solis Cohen, has just been completed.

The douche treatment is the most efficient form of water treatment in chronic disease, and its action is the most varied. Baruch, who has always insisted, and rightly so, on precision in method, devised an excellent douche table, which permits exact regulation of pressure and temperature. Douche apparatus has recently been installed in a number of hospitals in this vicinity, including the McLean Hospital, the Danvers Asylum, the New England Hospital for Women and Children, Dr. Millet's Sanatorium at East Bridgewater, the Butler Hospital at Providence, and our own Medical Baths in Boston. Dr. Blumer of the Butler Hospital says in his last annual report that "Hydrotherapy has been so productive of results that our baths are now used far beyond their capacity."

Dr. Baruch has established a hydriatic department at the Riverside Baths, in New York, to which physicians and dispensaries refer cases. The number of patients treated has risen from 2,146, in 1895, to 16,012, in 1902, — incontrovertible evidence, as Baruch says, of the increasing appreciation of the value of hydrotherapy. As a result of the efforts of Dr. J. J. Putnam, assisted by medical men and laymen, a hydrotherapeutic institute with facilities for all forms of hydrotherapy, owned and controlled by physicians, has been established in Boston, to which any physician may send patients. Although only opened seven months ago, the support given and the results obtained have been most satisfactory.

Baruch's douche apparatus is not the only invention American medicine has given to physical therapeutics. In 1891, Kellogg of Battle Creek devised the electric light bath, which, although in constant use to-day in the well-equipped clinics of Europe, remains almost unknown to American physicians.

As early as 1893, Dr. Peterson of New York urged that some of our medical schools give instruction in hydrotherapy. It is encouraging to read in the last annual announcement of the Cornell Medical School that to the students in small sections "will be demonstrated the various applications of water to the treatment of disease — such as baths, packs, douches, etc."

Among hospitals well equipped for other forms of physical therapy, the Royal Victoria of Montreal should be mentioned, which has excellent apparatus for electrotherapy. The facilities at the Boston City Hospital for x-ray therapy and the pioneer work of Dr. F. H. Williams are well known. No hospital in the world has so complete a set of Zander apparatus, numbering sixty-three pieces, as is to be found in the new department of mechanotherapy of the Massachusetts General Hospital.

From this brief sketch of the position hydrotherapy and other physical treatments occupy to-day, it is evident that this branch of medicine has attained a much higher stage of development in Europe than in America. It is a subject certainly worthy the attention of our leading clinicians, and it is to be hoped that our large hospitals, so excellent in other respects, will soon have facilities for physical therapy that will compare favorably with those of Germany, and that the facilities will be as intelligently used. But in order to insure the intelligent application of physical agents, it is necessary that instruction in physical therapeutics should be given in our schools.

DISCUSSION.

Dr. J. J. PUTNAM of Boston: These two papers are certainly very timely, and will be of great service. I shall not attempt to say anything about the scientific aspects of hydrotherapeutics, but simply of the efforts that are being made to place this means of treatment at the service of physicians in this city. Of course much can be done with simple means, but for many purposes an institution is needed, and such an institution we now have at 126 Massachusetts Avenue under the charge of Dr. Pratt and an informal committee of physicians.

Of course such an institution is very expensive, and without outside aid we could not have fitted up the rooms and obtained the necessary apparatus to carry on the work successfully. Our small establishment is now on a good footing, except that we still need the support and interest of physicians, and funds for the introduction of further apparatus.

Dr. G. T. Tuttle of Wellesley: We have been using hydrotherapeutics in some form at the McLean Hospital since the spring of '97, and in order to employ it to the best advantage I have tried to ascertain what

it really did for our patients, since it seemed to me that rather extravagant claims had been made for it. The effect desired was chiefly stimulating or tonic, and great care has been used to secure a good reaction; that is, a permanent return of blood to the surface vessels after cold applications. The problem has been to adapt the temperature of the water, the pressure under which it is delivered, and the time of its application to the strength of the individual so that this reaction may be as perfect as possible. Patients differ in regard to their ability to respond, and there is also a variation in the same person at different times; even healthy people should use caution in taking these baths when they are tired. The neurasthenic, if the bath is too vigorous, complains of exhaustion, which seems to contradict the claim that these baths increase the capacity for work. To determine whether this is so, a series of experiments has been conducted with the use of the ergograph with practically negative results. We could not obtain fatigue curves showing the great increase in work done after the bath that has been recorded by others. Observations on the pulse rate, respiration and temperature during the various stages of an ordinary bath show that they all vary directly with the temperature to which the individual is subjected; while the blood pressure varies inversely with the temperature, — hot applications lower it, cold applications raise it. The sudden fall of blood pressure is no doubt the reason why some people faint while in the hot air cabinet.

Considerable importance has been attached to the fact that some observers have found a large increase of red and white cells in the blood after various hydriatic procedures. We have been unable to confirm this, and, in my opinion, any increase of cells in the surface vessels after cold baths is purely a local phenomenon, and a disadvantage if long continued.

Theoretically, cold applications to the entire surface of the body at once should cause a flushing of the internal organs and an increased activity. Observations have been made by Dr. Otto Folin in our laboratory to determine whether such baths as we give really cause any increase in destructive metabolism of the body, with practically negative results.

The wet pack has been found extremely useful in cases of exhilaration or excitement for its soothing and even hypnotic effects.

While I have been unable to confirm many claims made for hydrotherapeutics, there are, in my opinion, many and sufficient reasons for its use.

Dr. R. T. Edes of Reading: There have been several points in these papers which have interested me very much, and I am glad that they were read together, as Dr. Millet shows that a very efficient use of this highly important agent can be made without complicated and expensive apparatus.

Dr. Pratt's paper, in its very thorough treatment, gave one the idea, although he did not exactly say so, that hydrotherapy is quite a recent introduction in Germany and that it was introduced into this country by Dr. Baruch.

In a report on "Therapeutics" for the BOSTON MEDICAL AND SURGICAL JOURNAL, 1872, I quoted from German authorities statistics on the subject, and in 1875 I read to this society a paper based on my experience of three years at the Boston City Hospital on the "Treatment of Typhoid by Cold Baths." This was published in the BOSTON MEDICAL AND SURGICAL JOURNAL and in the Second Series of the City Hospital Reports.

Of course, the subject is growing and developing. Much elaborate apparatus has been devised and the scope of its application much extended. Probably it is more scientifically understood but it is not absolutely new here.

Dr. Pratt: Certainly, as Dr. Edes says, the use of water in the treatment of disease is no new thing. Probably no therapeutic method is of greater antiquity. I regret that I failed to make it clear that I was dealing only with the development of scientific hydrotherapy. Baths as a curative agent were highly valued by Hippocrates. Galen considered cold water most important in fever, as did Celsus, Avicenna and Rhazes. But the origin of hydrotherapy on a physiological basis dates from the work of Winternitz in the third quarter of the last century.

Over a hundred years ago the distinguished New York physicians, Samuel Bard and David Hosack, following the teachings of Gregory of Edinburgh and Currie of Liverpool, used cold sponging in the treatment of fever. Somewhat later Nathan Smith of Yale College employed with success cold water in typhoid fever. But the influence of these men soon ceased to be felt, and water as a curative agent was forgotten, and hence this period has but slight historic interest and played no part in the development of the hydrotherapy of to-day.

It is certainly not generally known that the modern cold water treatment of typhoid fever, developed in Germany by Brand, Ziemssen, Jürgensen and others, was introduced into America by Dr. Edes. I shall take pleasure in giving him deserved credit in my published address.

THE PRACTICAL APPLICATION OF HYDROTHERAPEUTIC MEASURES.*

BY CHARLES S. MILLET, M.D., BROCKTON.

IT will be my purpose, in the short time that I shall detain you, not to discuss *all* the hydrotherapeutic procedures, but only those with which I have had a personal experience. These procedures, like so many other things in medicine, are at first perplexing and seem well-nigh impossible in private practice; but if they are analyzed a little, and one begins to use them, he will soon find that their application is as simple as it is effective.

The skin contains far more nerves, blood vessels and glands than any other organ; in fact, so numerous are the blood vessels that it is said that they will hold half of all the blood in the body. Its function is to convey impressions to the brain and other nerve centers, to carry off waste products, and to regulate body heat. In other words, it is the organ of sensation, the next most important sense to that of sight. It is a powerful excretory organ, sifting out from the blood carbonic acid gas, various other products of metabolism, and water, in which enormous quantities of pathogenic bacteria have been found.

The heat of the body is produced by the combustion of non-nitrogenous substances, chiefly in the muscles, and it is given off by perspiration and radiation from the cutaneous surface.

Hydrotherapy, then, has to do with sensation, excretion and heat radiation, and if we could only keep these facts in our minds when applying this sovereign remedy, the application would be

* Read before The Massachusetts Medical Society, June 8, 1904.

much easier; it would be oftener made; and the results would be more satisfactory.

Of course, in endeavoring to influence any one of these three functions it is impossible not to affect the others to a greater or less degree; but at the same time, it is not at all difficult to so use water as to vary these impressions and cause the one most desired to become prominent.

Furthermore, by applying water to the skin at various degrees of temperature and in various ways, we can, through reflex action, produce decided effects upon the mind, the central nervous system, and all the internal organs.

Let us first consider the treatment of fever, which is largely, if not wholly, due to diminished heat radiation; there is nothing that will produce quite so much perturbation in the average medical mind as an excessively high temperature. The personal experience of any man who has been twenty years in practice must have carried him through a disappointing period with so-called antipyretics, — the principal one used being acetanilide, I fancy. I well remember a case of typhoid fever, in which the temperature reached 105° before the end of the first week, that I treated with large doses of this drug, some fifteen years ago. The medical magazines at that time were teeming with articles, telling of the efficacy of these coal-tar preparations.

Convinced by the brilliancy of the results claimed, I proceeded to give it on alternate days, and in liberal doses. The effect upon the temperature was as marvelous as it was temporary; but the resulting anemia and peculiar lividity were most distressing. And when Dr. Fitz, whom I called in consultation, wondered at it, I must confess I did not dare to tell him how heroically I had dosed the young woman, — for I had not forgotten his method of showing us our mistakes in the classroom, and I feared he might use it here, the cause was so just.

The reign of drugs in the treatment of fever was, as you all know, very short, and we soon began to hear of Brand and the remarkable results which he had obtained by the use of cold baths in typhoid; and while the idea has been very generally accepted, and its great value acknowledged, yet I firmly believe that his method of using water is so often modified that it would be very hard for the originator to recognize it. The so-called "typhoid bath" of to-day usually consists of sponging with cold water; and while this is quite sufficient when the temperature is not over 104°, any rise above that is not properly treated unless the tub, with friction while in the water, is used. On the other hand, it is to be remembered that reduction of temperature is by no means the main object in view, yet the strengthening of the heart and the calming of the nervous system are not obtained without a gradual fall in this respect.

In any given case, the use of water must be in the nature of an experiment, but failure to produce marked signs of improvement must not deter one from persisting; but rather should cause deep thinking, lest a measure far more productive of good than drugs shall be neglected. Take, for example, a case of scarlet fever which I once saw, — a strong, rugged girl of sixteen, so large and well developed that she looked twenty; there were other cases in the family, so that when she was taken sick it seemed very probable that it must be the same disease; the trained nurse had just taken her temperature when I went in, but said nothing. Placing my hand upon the patient, I found the skin quite cool and said that I did not consider her very ill, whereupon the nurse showed me her thermometer, which had registered 106°; and then when I counted her pulse, I found it to be 140. The extremely high temperature so startled me that I neglected to consider the other symptoms and cold sponging was ordered; the next day exactly the same condition was found, — the skin was cool, but the temperature and pulse were very high, and again the same mistake was made, the belief that the temperature must be reduced being paramount; and a more persistent application of cold baths was insisted upon. And so, on a third day there was found to be no change. It then dawned upon me that something else must be done if that girl was to live, and the nurse was told to wrap her up in a hot, wet sheet, — or in other words, to give her a hot pack.

The result was so remarkable as not to be forgotten; the eruption, which had been delayed, almost immediately appeared, and the pulse and temperature rapidly fell to not much above 100. The explanation is, apparently, that the blood vessels in the skin were so irritated by the poison of the disease as to be in a state of tonic contraction, so that the application of cold had no effect upon them.

Spencer says that *science* is nothing but common sense, systematically and thoroughly applied. Therefore, one can use a little here, and be guided by the condition of the patient, in determining whether the water should be hot or cold; its application long or short, and with or without force. If the pulse is high in tension and full in volume and the skin hot, a cold bath will produce better results, even though the patient cries out against it. I have seen a boy of five scream frightfully for ten minutes, every four hours, for days when the nurse gave him a cold bath, then dropping off to sleep almost immediately, his temperature and pulse being perceptibly improved thereby, in spite of his fright.

If it is true that the heat of the body depends upon and is regulated by the action of the skin, and is kept at a normal degree by the automatic working of this organ, and if it is true that an abnormal rise is in every case due to an impairment of this action, then certainly in hydrotherapy we have a method with which we can at will influence enormously one of the most important functions of the body.

To reduce fever, three kinds of baths are used: that with a sponge, the water containing perhaps alcohol or soda; the cold bath, either in a tub, or in bed with a rubber sheet; and the warm bath, gradually reduced. The question is, of

course, what shall determine our choice; to which the answer is,— *Experiment*; it does not matter which, so long as a good reaction is obtained. Long before any damage can be done to the patient, his own senses or the observation of his nurse, no matter how inexperienced, will give the desired information.

The sponge bath will do for febrile conditions not severe enough to cause any anxiety, and which will evidently be of short duration. But any infectious fever which is at all severe, is certainly poorly treated if a full tub bath, or a bath in bed, with lots of water and friction, is not employed. In order to obtain the confidence of the relatives, it is well to begin with a bath of 100°, and run it down to 90 in about ten minutes; the head should be wrapped about with a cold, wet towel, or the patient will be liable to faint. This is an excellent bath to give a child who has bronchitis, pneumonia, measles, or any other acute infection; and if is is not effective in producing sleep, the temperature of the water should be reduced two or three degrees every three or four hours. If no bath tub is available, an ordinary wash boiler or wash tub is a good substitute. But in a severe case of acute febrile disease in an adult, — of which typhoid fever might be called the type, — it will be necessary to use cold water, which is again mentioned in order to emphasize the point that unless friction is used with it, there is liable to be little or no reaction. The term "reaction" is so often heard in connection with hydriatics that a definition of it might not be out of place; a perfect physiological reaction takes place when the blood, having been driven out of the surface, is caused to return with redoubled energy. In other words, the restoration of heat after heat abstraction is the one thing essential. If the blood is not in the cutaneous vessels to begin with, it is necessary to first apply heat; if one realizes that the nerve filaments which convey the sense of cold act like lightning, while those which carry the heat sense act more slowly, it is very easy to understand why it is so often necessary to apply the latter for the long period; and why, when warmth is alone used, the reaction appears only after a time. Often this is desirable, — say, when one wishes to produce sleep and does not care to arouse the nervous system. But sometimes it is impossible to produce rest and quiet without stimulating the nerves. Such a condition is present in melancholia or acute mania, which it has been my good fortune to see greatly helped by means of bathing. Here the patient should be set in hot water, and a pailful of cold should be quickly and forcibly thrown over the shoulders. It is truly marvelous the way an extremely restless patient will quiet down and go to sleep after such rigorous treatment. Such cases, too, almost always refuse to take medicine; and if they do not, the hypnotics are ineffective except in lethal doses. *It is neither difficult nor dangerous to give baths.*

The hot wet-pack is relied upon by most physicians in eclampsia, and in fact whenever the kidneys are blocked or diseased. But the result obtained is not so much due to vicarious action, as it is to the withdrawal of blood from the internal organs. If used continuously, — I mean day after day, — in chronic Bright's disease, it is better to supplement the heat with a short, quick, cold affusion, and rubbing.

The water poultice is very beneficial in pneumonia, and in all acute pulmonary affections. This is made of three layers of old linen, which are wrung out of cold water and wrapped around the chest, and then dry flannel is placed outside of that. This should be wet as often as it gets warm.

Chlorosis, secondary anemia, chronic, pulmonary and organic heart diseases have all been decidedly benefited by systematic bathing. In these it is advisable to first produce warmth to the point of perspiration, — either with a hot air cabinet, or, better, by a sun bath, — and then to give the patient a warm shower, and to follow that with cold water through the hose. If possible, perambulatory cases would better be treated at a place where medical baths are given, — for a limited time, at least, — after which, if necessary, the treatment can be continued at home. If the physician would go with his patient and see him take a bath in the institution which Dr. Putnam and others have so generously placed at our disposal, he would very quickly discover that there is something in hydrotherapeutics other than charlatanism.

The local application of heat and cold acts on the part treated in a similar manner as the full bath does on the whole body. If a joint or muscle is very hot, apply ice; but if the disease is of a subacute nature, and the circulation and function impaired, first apply heat, and then cold, perhaps with gentle friction. Ice is too often used to need more than a passing word. It is certainly the best substitute for opium, but should not be used constantly, because it will finally cause paralysis of the vaso-dilators. I do not think it is applied over the precordia with the frequency that it should be; placed here, its effect is exactly like digitalis; and the beauty of it is, that it acts with great rapidity; that it has no cumulative action, and that it does not disturb the stomach. In cases of collapse or shock, it is as important to put an ice bag over the heart as it is to apply heat to the extremities; and how often is it done? Ice over the epigastrium will greatly relieve the thirst which follows abdominal operations.

As I said in the beginning, my remarks have been in the nature of a personal experience; and with an apology for the crudeness and cursory way in which I have treated the subject, I will close, — adding an urgent solicitation that you will give a remedy which is as powerful as it is harmless, the confidence which it deserves. Certainly, the skin, by which we are in close communication with the central nervous system, the heart, and in fact all the internal organs, should never be neglected; and half-hearted care and attention are worse than absolute neglect, because they deceive the physician himself.

SACRAL SPINA BIFIDA, WITH REFERENCE TO THE SKIN REPRESENTATION OF SACRAL NERVE ROOTS.

BY E. W. TAYLOR, M.D., BOSTON.
From the Neurological Department, Long Island Hospital, Boston.

THE following case is reported as a contribution to the segmental skin representation of sacral nerve roots, and also for its general clinical interest.

The patient, J. F. McC., thirty-three years old, unmarried, by occupation an amalgamated gold miller, was first admitted to the Long Island Hospital, Feb. 12, 1903. He was discharged, and readmitted Jan. 1, 1904, for the treatment of trophic ulcers and asthma.

The family history has no bearing on the present condition. The matter of chief interest in the personal history is the presence of a sacral spina bifida, from which his disabilities, excepting the asthma, come. He has had asthma since childhood, and as a child had measles, mumps and "cholera infantum." On several occasions he has had cystitis. He has always had incontinence of urine, and wears a urinal constantly. His bowels move irregularly, and coughing is apt to force out a small amount of feces; if the desire for defecation is not soon gratified he occasionally has incontinence. This has remained unchanged throughout his life. Five years before entrance at Long Island, he was treated for three months at the Boston City Hospital for an ulcer on the side of the right foot at the base of the little toe, with necrosis of bone. The ulcer finally healed. Four years later a similar condition appeared on the left foot, for which he was again treated at the City Hospital, with final healing. He was admitted to the Long Island Hospital with a recurrence and necrosis of bone. He has always noticed diminution of sensation over and above the tumor caused by the spina bifida and in the legs and feet. Except when struck the spina bifida has itself caused him no trouble. On those occasions, however, when it has been accidentally struck, he says "he drops like a shot," and has a tonic convulsion of the legs, the duration of the convulsion depending upon the severity of the blow. He makes the statement that "he was once paralyzed for three days as a result of a hard blow received there, and was in agony from a feeling of pins and needles over his legs." Except for the awkwardness due to deformity of his feet he is perfectly able to walk, and he maintains that his sexual capacity is unimpaired. He has had no venereal disease, has been very moderate in the use of alcohol and tobacco and has been able to learn and successfully apply a trade requiring physical effort and manual dexterity. In spite of urinary and fecal incontinence his companions have not recognized his disabilities.

Physical examination gives the following results: Well developed man, with no obvious sign of disability except the easily noticeable deformity of the feet. Tongue, chest, except at time for asthmatic rales, heart, abdomen and abdominal organs normal. Directly over the sacrum (see Fig. 1) is a hard, doubtfully fluctuant, round tumor, 2½ by 1½ inches in diameter, the upper level being an inch and a half below the posterior superior spine of the ilium, and the lower between two and three inches above the anus. Pressure over the tumor produces pain. Further examination made March 19, 1903, showed that gentle touch over the tumor was not felt; pin prick very slightly felt as touch (pressure?); outer side of left foot cooler than inner; loss of muscle sense in toes; legs, in general, cold, cyanotic and more or less discolored; tremor of thigh muscles (excitement?); knee jerks normal; no ankle clonus; plantar present; no front tap; no Achilles; no cremasteric; abdominal and epigastric reflexes also not obtained. The feet both show marked clubbing, which is apparently gradually increasing, interfering considerably with walking.

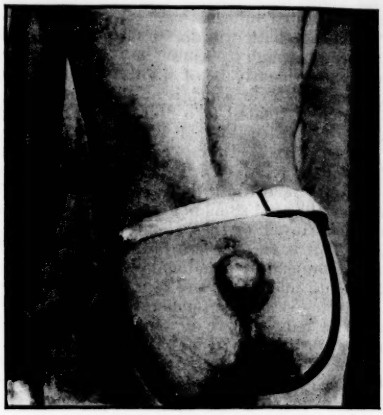

FIG. 1. Spina Bifida; sacral; showing also anal protrusion.

There is slight Romberg, due, he thinks, to the deformity of the feet. There is a scar on the under surface of the right foot, at the tarso-metatarsal joint. On the left foot, a sinus over the fifth metatarsal joint extends upwards about an inch and a half; bone is necrotic; moderate purulent discharge; considerable swelling of the foot, especially of the dorsum, with some induration. There are also slight excoriations in both gluteal folds. Except for the limitation of motion dependent necessarily upon the deformity of the feet, no motor paralysis is discoverable. Flexion at the ankle and movements of the toes are possible, though naturally imperfect. Movements at the knees and hip are perfectly free and made with good strength.

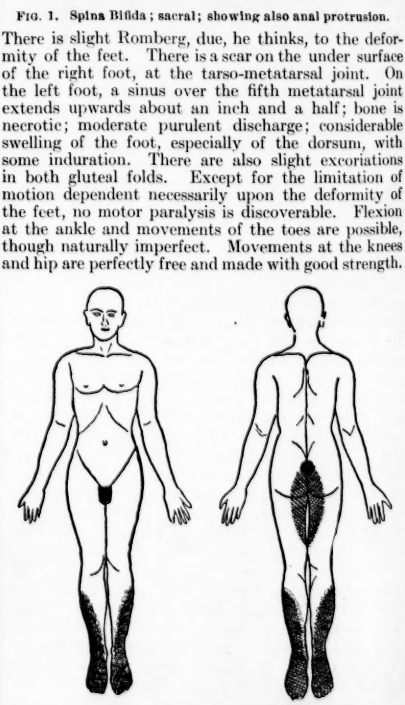

FIG. 2. Areas of anesthesia, shaded.

There is protrusion of the anus. (See Fig. 1.) The sensory loss is as indicated in the diagrams (Fig. 2). The areas deeply shaded are practically completely anesthetic, but the anesthesia everywhere fades out at the borders into the normal.

Treatment at the hospital resulted in a final healing of the foot ulcer, and in an amelioration of the asthmatic condition, and he was discharged. A recurrence of ulceration in both feet led to his return a few months later. In general, the condition remains unchanged, excepting, as he thinks, for an increase of the club-foot deformity; at a recent examination, also, the plantar reflex is reported as absent, instead of present as before noted. The patient remains physically well; the ulcers and club feet combined interfere with walking, which is otherwise perfectly possible, and his scrupulous care has prevented the complications likely to result from urinary incontinence.

The pathological condition in this case is undoubtedly in general this: a defect of development of the sacrum, with a resulting spina bifida, producing symptoms referable to the sacral cord, through involvement of its nerve roots, of predominant sensory character. The tumor is too low for direct involvement of any part of the functionally active cord, the result, however, being essentially the same from interference with sensory conduction through the lower nerves which presumably form part of the walls of the sac. The question of operation in such a case is naturally not to be considered; first because the tumor is so small as to be but a slight discomfort, and secondly because relief by surgical means in a spina bifida, of the type of a meningo-myelocele, is anatomically impossible. The fact that marked sensory symptoms have resulted from this somewhat insignificant-appearing tumor is sufficient indication of the direct involvement of nerve roots. It is also a fair presumption, though naturally one not capable of present demonstration, that in such a malformation, if the upper sacral nerves are involved the lower ones would also be affected. A study of the distribution of the anesthesia, therefore, becomes a matter of interest and importance in the determination of the peripheral areas of sacral segments.

There is still a wide divergence of opinion regarding the segmental distributions of the cervical, lumbar and dorsal nerves, due in part to a possible variation in different individuals, and to the failure to recognize the tendency toward overlapping of the various nerve areas, as pointed out especially by Sherrington; the fact that relatively few cases have been studied with sufficient

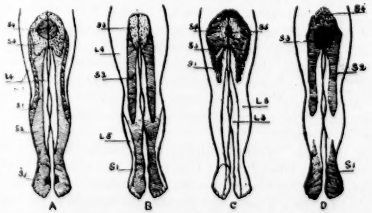

FIG. 3. Sacral Segments after, A, Kocher; B, Thorburn; C, Starr; D, Head.

care, both before and after death, is, however, more directly responsible for the existing differences. Reference to the accompanying diagrams (Fig. 3) illustrates this point with regard to the sacral nerves, to which alone it is desired to call attention. The general rule formulated by Herringham and confirmed by Paterson for the leg that, of two spots on the skin, that which is nearer the preaxial border tends to be supplied by the higher nerve, and of two spots in the preaxial area, the lower tends to be supplied by the lower nerve, and of two spots in the postaxial area, the lower tends to be supplied by the higher nerve, is in general confirmed by all investigators. The details, however, differ widely. Starr[1] contracts the sacral segments almost wholly to the saddle-back area. Kocher represents the widest departure from this distribution in giving an extensive distribution to the second sacral segment in thigh, leg and foot. Thorburn and Head stand between with a representation of the second sacral segment chiefly in the thigh, and of the first in the foot and part of the leg. It is altogether probable that such a divergence does not correspond to the facts as observed in different individuals, and that there is more consistency in the distribution than here represented.

The case here reported is naturally of far less value than if exact knowledge of the nerve lesions were obtainable; nevertheless, the clean cut character of the anesthesia points to a destructive process of extreme degree which is of significance as a contribution to the general subject. On the ventral side of the body the penis, scrotum, leg and foot as represented in the diagrams (Fig. 2) were anesthetic. The sensory supply of the external genitalia from the second, third and fourth sacral segments is very generally conceded, and this case offers nothing noteworthy in this respect. The anesthesia of the front of the leg and foot is, however, of interest. Kocher alone of the investigators to whom we have alluded gives a sacral representation (first and second nerve roots) over the front of the leg. The area he maps out corresponds almost exactly to the anesthesia found in my case, but in view of the dorsal distribution, it appears probable that the fifth lumbar nerve is also involved, its lesion constituting this well-marked anesthesia wholly or in part. This area is generally conceded to be innervated from the fifth lumbar segment. The dorsal anesthesia, to which I wish to call special attention, evidently cannot be explained if Starr's diagram, as represented in Fig. 3 C, be correct, nor can it be made consistent with Kocher's scheme, which supplies the back of the leg unbrokenly with sacral nerves. On the other hand if the plan as outlined by Thorburn and especially by Head be followed, the

[1] Starr: Am. Journ. Med. Sc., iv, p. 15, 1892. Fig. 3, C is after the diagram on p. 29 of this article. In his recent book, "Organic Nervous Diseases" he makes the second sacral segment correspond to the first in the earlier diagram, and extends the first segment down the back of the leg into the foot, bringing the distribution into much closer relationship with Thorburn's and Head's ideas. There can be little doubt that this is a more accurate representation of the facts, than the earlier diagram, which apparently does not account in any way for the second segment.

similarity to the anesthesia as seen in my case is at once apparent. Thorburn merges the area of the first sacral segment with the second, which occupies a strip, extending somewhat below the knee. Head pictures an area intervening between the first and second sacral segments, which is accounted for by lower lumbar segments. This arrangement of the areas is strikingly like that observed in my case. Assuming that the fifth lumbar as suggested above is involved in the spina bifida, the extensive dorsal anesthesia of the legs finds an explanation. The intervening space is in all probability not supplied by sacral nerves, which again, in general, coincides with Head's view (Fig. 3, D). The distribution of the anesthesia in the saddle-back area does not find an exact counterpart in the diagrams from the investigations mentioned, inasmuch as it includes more of the inner surface of the thighs, and does not extend so far down the leg. The fact may be taken for what it is worth as indicating a variation in sensory distribution of the lower sacral nerve roots.

The only motor disorders manifest in the case are marked clubbing of the feet, and protrusion of the anus. The foot deformity is no doubt in part due to faulty shoes, as suggested by Dr. E. H. Bradford.

The case throws no added light on the exact location of the sphincter representation in the cord. It is however, a matter of practical interest that in spite of absolute urinary incontinence and practically a similar condition of the rectum, the patient has been able to work and associate with others, without disclosing his disability. He has also avoided any serious degree of cystitis, and trophic disorders, excepting ulcers of the feet to which allusion has been made in the clinical history. Finally, it is worthy of comment, that in spite of practically complete anesthesia of the penis, his sexual desire and capacity, so far as he knows, have in no way suffered.

A somewhat recent paper [2] by Van Gehuchten discusses, on the basis of a lesion of the canda equina, the question of the centers of micturition, defecation, erection and ejaculation. His opinion is that the primary centers for these functions are for the first three wholly and for the last partly localized in the sympathetic ganglion of the hypogastric plexus, to which are added the centers lying in the lower cord, which in turn are under control of the central cortex. He is furthermore of the opinion that the sympathetic centers may functionate, independently of the cerobrospinal centers, as may be observed in infants, and in adults with lesions of the conus, or cauda equina. In my case voluntary micturition appears to be wholly abolished, whereas defecation is under relative control, and the sexual functions are apparently preserved. The case, therefore, bears out in part Van Gehuchten's views.

It is also of interest that in spite of anesthesia of the feet, the ability to walk has been maintained and appears to be hindered only by the existence of the clubbing of the feet. The patient presents none of the uncertainty of station which one invariably finds in tabes, for example, with an equal degree of disordered sensibility.

The points of significance which a study of this case brings out are:

The existence of areas of anesthesia, from lesion of sacral nerve roots, which in general coincides with Head's description of their skin representation: [3]

The retention of sexual capacity in spite of extensive destruction of the sacral nerve roots;

The absence of marked disturbance of gait in spite of plantar anesthesia;

The practical possibility of physical cleanliness with both vesical and rectal incontinence.

OPERATIONS ON THE STOMACH, WITH REPORT OF CASES.

BY JOHN C. MUNRO, M.D., BOSTON,
From the Surgical Clinic, Carney Hospital, Boston, Mass.

(Continued from No. 7, p. 190.)

No. LXII. Female, thirty-two years old came to me in February, 1903, with a long history of many operations.

Within the last two or three years she had had an exploratory operation for supposed movable kidney, a cholecystectomy, an operation for adhesions following this latter, nephrorrhaphy, then later an appendectomy. From all these operations she had derived no relief, and she came with persistent pain night and day, nausea, occasional vomiting and general discouragement.

Operation was done at the Boothby Hospital, and the gall bladder, full of gallstones, was removed. The adhesions in that part of the abdomen were formidable and made the operation difficult. After operation she complained steadily of pain deep in the abdomen, not severe, but persistent and dull and followed by vomiting. She begged for further operation for relief, which was unwisely consented to. Under chloroform the abdomen was again explored. Nothing definite was found beyond the general mass of adhesions dragging the liver downwards and pulling the duodenum far to the right and forwards. In separating the adhesions the duodenum was opened and examination through this tear showed the pylorus free and without induration. The tear in the duodenum was closed, but the tissues were so abnormal that it seemed wiser, if possible, to prevent leakage by doing a gastro-enterostomy at once. So the abdomen was opened in the median line and an anterior button anastomosis made at the same time.

About ten days afterwards, leakage of bile and pancreatic fluid appeared in the lateral wound and this continued for a number of weeks.

At the time of the first operation there were evidences of pulmonary tuberculosis. These increased after being in the hospital a few weeks, while the biliary sinus closed gradually. The patient steadily lost ground and was sent into the country on account of her tuberculous condition, where she probably died shortly afterward.

No. LXIII. Female, thirty-nine years old, referred to me by Dr. Hodgkins of Castleton, Vt., in July, 1903.

She had been under medical treatment for stomach trouble for two years, the symptoms steadily growing

worse. In February, preceding, she began to have hemorrhages, much pain after eating, and tenderness in the epigastrium. All these symptoms had steadily increased, with some loss of weight.

Operation, August, at the Carney Hospital. The stomach was found slightly dilated, the pylorus apparently normal, but alongside of it a small area of thickening suggesting an ulcer. A posterior gastro-enterostomy, with clamps and sutures, was made and the wound closed in layers.

The patient's stomach symptoms at once ceased, and at the end of four weeks she returned home, eating regular food without any symptoms. During convalescence there was a stitch abscess, due to some technical error at the time of operation. Three weeks after leaving the hospital vomiting began again and she returned in November with a history of persistent vomiting day and night, coming on one to two hours after eating. No hematemesis. She stated that just before the vomiting attacks recurred, she had fallen forward, striking the abdomen; but it is doubtful if that had any direct influence in the relapse. She still complained of severe pain in the left side, relieved by vomiting or catharsis.

At the second operation there were no adhesions to the old scar, but a portion of the omentum at the right border of the stomach was found adherent far to the left of the median line, pulling the right portion of the greater curvature leftwards and lapping this portion of the stomach over the main portion. This adhesion was freed and the raw ends covered over. At the anastomosis there was a thin sheet of adhesions puckering the distal arm of the jejunum close to the anastomosis so that the gut was folded upon itself into a Z-shape loop, apparently blocking the lumen to a considerable extent. The anastomotic opening was free and without evidence of constriction. The sheet of adhesions was ligated and freed, the jejunum being easily drawn out to its normal straight line. In addition to this the mesentery opposite the opening was shortened upon itself and sutured, in order to counteract any tendency of the mesenteric border of the gut to form a valve. Nothing abnormal elsewhere was found. The wound was closed in layers and the patient recovered promptly and was discharged, eating solid food without vomiting and perfectly well. It is probable that the sepsis which had produced the stitch abscess, infected at the same time the peritoneum at the site of anastomosis, making the troublesome kink. Almost as soon as the patient had arrived at her home vomiting returned, and when heard from in April last she had vomited persistently ever since, some hours after eating. Efforts were made to induce her to submit herself again to operation, but without success. I have no question but that the condition could now be entirely relieved.

No. LXIV. Male, twenty-nine years old, entered the Carney Hospital in September, 1903. Referred by Dr. Smithwick and Dr. G. N. Jones, with a history of dyspepsia for two years, gradual in its onset; distress after meals and latterly even before meals. The duration of the pain varied and relief was obtained by drinking hot water, fol lowed by eructation. He had never vomited and had never had nausea. He had been under all forms of medical treatment and diet, but without benefit. He had lost weight, was unable to work on account of his nervous condition, and operation was advised in the hopes of finding some definite organic cause. Lavage had shown some blood in the later washings. A small, diffuse mass could be felt in the region of the pylorus, moving with respiration. This region was the seat of his pain and tenderness.

At operation the stomach was found moderately dilated. There were no outside evidences of ulcer. The pylorus was free. There were no adhesions. Nothing could be found to account for the trouble beyond the possibility of minute ulcers or a small ulcer of the duodenum undetected from the outside. Posterior gastro-enterostomy was done in the usual way, and the wound was closed in layers. The patient convalesced satisfactorily and at the end of two weeks was discharged, able to eat almost anything.

February, 1904, he wrote that he had not derived great benefit. He had gained weight gradually, and strength, but was still troubled a good deal with gas. Up to Dec. 1 there had been no return of his former trouble. Then he began to have the same distressed feeling and had had several attacks that persisted pretty steadily for some days. He described his trouble as lasting for about a week, followed by relief for two weeks and then returning. He is living regularly and his work is easy, but it is evidently a functional rather than an organic trouble.

No. LXV. Female, thirty-seven years old.

In all probability addicted to the use of opium and cocaine. Referred to me by Dr. Twitchell in December, 1903. She was a marked neurasthenic and came with a history of attacks of faintness, severe pains across the upper abdomen, bleeding for a year, constipation, and enforced limitation in diet for a number of years. She complained of distress an hour or more after eating, and described it as very severe, the griping being followed by flatulence and distention. The diagnosis was extremely uncertain and an exploration was advised on the chances of finding some organic trouble.

At operation, at the Carney Hospital, the liver was found prolapsed, the stomach prolapsed and dilated, the transverse colon was found adherent to the sharp edge of the extreme right portion of the liver, dragging this portion of the lobe two to three inches past the main portion, where it was held by old, firm adhesions, backward against the duodenum and gall bladder, the latter being buried beneath the adhesions. The gall bladder after being freed appeared normal. The pylorus was found irritable at examination, but admitting the finger. Examination of the stomach, pelvis, etc., negative. All the adhesions were freed, the colon was replaced, and a posterior gastro-enterostomy, in the usual way, was done. The mesocolon was found abnormally adherent to the posterior wall, suggesting patches of scar tissue. The wound was closed in layers. The patient made a satisfactory convalescence and was discharged in two weeks, eating the regular food without symptoms.

Since her discharge it has been reported that the patient has had more or less return of her old trouble, but whether due to her neurotic condition or to any true stomach lesion is very doubtful.

This case (No. LXV) with Nos. LXII and LXIV are pretty good examples of the sort of case that should be let alone. When the neurotic element is predominant, even if there is some slight organic lesion to start the explosion, it is doubtful if anything more than temporary benefit will be gained by operation. Such cases are best treated medically and psychologically, judging from this limited experience.

No. LXVI. Female, twenty-six years old, was referred to me by Dr. Johnson of Winthrop, with a history of persistent hemorrhage from the rectum, supposedly from hemorrhoids. She had had several

pelvic operations in times past and came with a history of prolapse and rectal bleeding for two years, with poor appetite and indigestion for some months.

At operation for the hemorrhoids practically nothing abnormal was found to account for the hemorrhage, but what small varicosities there were, were clamped and cauterized.

About a week after operation she had a severe hemorrhage from the bowels, with dark stools, repeated in a few days, and it was evident that the blood had not come from the rectum. She complained at the same time of pain in the stomach region and was evidently losing blood from some region higher up in the intestinal tract. A more careful investigation of her history pointed to old gastric trouble, and at the second operation, at the Carney Hospital, the liver was found prolapsed, the stomach markedly prolapsed, the lesser curvature being at the level of the umbilicus, the gall bladder was adherent to the omentum by old adhesions and drawn out of its normal position. Around the duodenum the adhesions were more marked. Most of these adhesions were separated and ligated, and the gall bladder was sutured to the liver in its normal position. Exploration of the pelvis showed nothing abnormal. An examination of the intestines showed nothing abnormal except for some dark contents suggesting blood. The dilated U-shaped stomach was all that could be found pathologically. Consequently, a posterior gastro-enterostomy, in the usual way, was performed. The mesocolon was found adherent to the posterior wall so that the lesser cavity could not be explored. The gastrohepatic omentum was shortened, lifting the lesser curvature to its normal position. The wound was closed in layers. The operation was a long one and the patient had moderate shock. Examination of the stomach before operation showed stasis, dilatation, free hydrochloric acid. The patient was discharged in about two weeks, enjoying ordinary diet and with a better appetite than she had had for years.

In April she reported that after leaving the hospital she was well for a month, when she began to vomit again, at first in small quantities. She sometimes vomited at once after eating and at other times several hours after. Occasionally she would go an entire week without vomiting, only to have it return every day for a short spell. No difference in diet affected the vomiting. She had had no hemorrhage, was looking well, and had not lost weight. By percussion the stomach seemed to be somewhat prolapsed and dilated, the lower border being at the level of the umbilicus. She was urged to re-enter the hospital for a second operation, with the idea of having an entero-enterostomy or whatever other procedure might be found necessary.

This case and No. LXIII were most disappointing. There must be some technical error to explain the relapses, but I feel so sure that it can be overcome by an entero-enterostomy or a pylorectomy that I would urge another attempt with great confidence.

No. LXVII. Female, forty-nine years old, entered the medical side of the Carney Hospital in April, 1904, after an attack of vomiting for three weeks, latterly persisting day and night, in which she had never noticed blood nor coffee grounds. The patient was very sick, with dry skin, and in bad general condition.

At operation, at the pyloric end of the stomach and the duodenum were old adhesions to the gall bladder and neighboring region, pulling the gall bladder to the left and apparently obstructing the duodenum. After freeing these the pylorus was found to be open, but with a slight thickening close by it as from an old scar. Elsewhere in the stomach nothing abnormal could be detected. A posterior gastro-enterostomy was done in the usual way and the mesocolon was found firmly adherent to the stomach towards the pyloric end. A hurried examination of the abdomen elsewhere showed nothing pathological. The wound was closed in layers.

This patient did not do well after operation. The vomiting was relieved somewhat, then returned again, and three weeks after the first operation the abdomen was reopened and the anastomosis was found free, with apparently excellent drainage into the jejunum. There were a few adhesions of the proximal portions of the gut to the stomach, not causing a kink. At the mesenteric edge of the proximal portion of the gut opposite the edge of the anastomosis, there was thickening of the gut with radiating scars of the peritoneal coat, so that the lumen was partially closed. The proximal portion of the jejunum was a little heavier and more dilated than the distal. The thickening and scar suggested peptic ulcer as the occlusion seemed to be internal and not from any external lesion. Entero-enterostomy was made with clamps and sutures and the wound closed in layers. Vomiting persisted after this second operation and the patient steadily lost ground and died in a few weeks.

Autopsy by Dr. Magrath. Appendix and lymph nodes normal. Transverse colon widely distended with gas. Pylorus adherent lightly by fibrous adhesions to liver. Opening in posterior wall of stomach 2.5 cm. cummunicating with the small intestine. Pylorus admits tip of finger; 50 cm. from beginning of jejunum is anastomosis. Left pleural cavity shows fibrous adhesions. Right normal. Pericardial fluid 250 cm. Myocardium flabby, left ventricle dilated, 9.5 cm. in depth. Lungs alike, voluminous. Base of left slightly increased in consistency, due to small areas of focal pneumonia in a region of partial atalectasis. Both lungs edematous. Spleen 11 cm. in length; pulp slightly increased, composition normal. A coil of ileum 15 cm. from the cecum was united by fibrous adhesions to the floor of the pelvis. Liver and kidneys negative. Aorta normal.

The only cause for the vomiting that seemed possible was the dragging of the ileum by its pelvic adhesion, overlooked at operation because examination of the proximal half of the small intestine failed to show any signs of obstruction lower down. This dragging may have caused the vomiting by reflex action; there certainly was no obstruction.

No. LXIX. Female, fifty-four years old, entered the Carney Hospital in March, 1904, on the medical side, with indefinite gastric symptoms. She was transferred to the surgical side, and under operation a gall bladder full of stones, and an enlarged mass in the region of the pancreas, supposed to be chronic pancreatitis, was detected. The stomach was found prolapsed but not dilated. She gained somewhat, but a month later the gall bladder fistula was reopened because of return of supposed pancreatic symptoms. The stomach began then to give her trouble and the patient was fast becoming unable to hold any food. A gastro-enterostomy was advised as a temporary measure. At operation the retroperitoneal growth had increased and a section from this mass showed, on examination, that the tumor was a retroperitoneal sarcoma and not a chronic pancreatitis, as had been anticipated. A button anastomosis was made and the wound closed.

The patient derived relief from the anastomosis, but gradually failed and died of malignant exhaustion a few weeks later.

No. LXX. Female, forty-four years old, referred by Dr. H. D. Arnold, entered the City Hospital in September, 1901.

A year and a half previously she had vomited blood and was fed by rectum for three weeks. Soreness in the epigastrium persisted, and six months before entrance she had had severe pain which had recurred off and on ever since. There was no history of passing blood by rectum, and she complained of general weakness, soreness in the epigastrium, and sharp pain not related to taking food. Gastric analysis showed free hydrochloric acid present; no stasis; a slight quantity of blood and pus in the washings.

At operation the stomach was found normal in size and on the anterior wall was an indurated, round ulcer midway in the lesser curvature. A posterior gastro-enterostomy, without clamps, was done with silk and catgut. Exploration through the stomach opening showed an ulcer with slightly raised, indurated edges and a more or less fissured base, in the anterior wall. Abdominal wound closed in layers.

Patient improved a good deal after operation, but had some vomiting, and two weeks after operation developed phlebitis of the left leg. She then gradually improved and her vomiting practically ceased and she was discharged from the hospital in fair condition.

In January, 1903, over a year afterwards, I was again asked to see the patient and learned that she had had no vomiting after return from the hospital, but that recently she had had more or less dyspepsia and had again been obliged to limit her diet. For two or three months she had complained again of the griping pains, and latterly these pains had been as severe as ever. Constipation had been a marked symptom. Examination showed in the left hypochondrium and umbilical region a tumor, superficial, hard in the left lower portion, and merging upwards and to the right, towards the right hypochondrium. The tumor was apparently in the stomach and exploration was advised.

At the second operation, at the Boothby Hospital, there was found an excess of abdominal fluid and a large mass in the stomach at the site of the old ulcer, with infiltration in the walls extending into the omentum and colon and apparently throughout the abdomen generally. There were extensive adhesions of the intestine to the stomach and omentum, but the anastomosis was found patent. The old ulcer had either degenerated into a carcinoma or was already carcinomatous at the time of the first operation and not recognized. Nothing more could be done and the wound was closed.

The patient lived several months fairly comfortably and died of general carcinoma.

The twenty-four cases from No. LXXI onwards include the more or less satisfactory results from anastomosis where the lesions were not malignant. The operations have been done too recently to make them of any value on the basis of end results. But the immediate results have been satisfactory and they are offered for what they are worth on that basis, and because they illustrate in the operative findings varied and interesting pathological conditions for which clinical explanations can usually be found.

No. LXXI. Female, forty-four years old, entered the City Hospital in November, 1902.

Had had bilious attacks, with vomiting and headache, ever since she was twelve years old. For three weeks she had had considerable vomiting, coming on an hour or two after eating, with epigastric pain, relieved by the vomiting. Had never vomited blood until two days before entrance, and had lost twenty-five pounds in the last three years.

At operation a dilated stomach, with well-marked scars at the pylorus, was found, without evidence of its being malignant. There were a few old adhesions of the omentum to the duodenum. The gall bladder was negative. A gastroduodenostomy, by Finney's method, was done and the wound closed in layers.

Three days after operation she had some vomiting which was relieved by lavage. The vomiting then ceased and the patient steadily convalesced, and was discharged a month after operation, without gastric symptoms and in good general condition. Her later history has been lost sight of.

No. LXXII. Female, thirty-three years old, entered City Hospital in November, 1902. She had been operated upon in the gynecological service a month before, for tubal and ovarian trouble. She was then transferred to the medical service, on account of almost continual vomiting day and night, which continued in spite of treatment. Her history showed that four years before entrance she had had a rather severe attack of vomiting, with epigastric pain lasting a week, with a little blood and bile in the vomitus. She then had no further trouble up to four months before entrance, except that she had been obliged to steadily restrict her diet in order to avoid gastric distress. At transfer to the surgical side the patient was seriously ill, with hollow, flushed cheeks, tender epigastrium and persistent, exhausting vomiting.

At operation the duodenum and pylorus were found firmly held to the posterior wall by old adhesions of unknown origin. Some of these were ligated and freed. No growth could be felt in the stomach. An anterior button anastomosis was made as quickly as possible, the patient being too ill to allow of careful examination. The upper jejunum was distended beyond normal, but it was impossible to determine whether it was due to any pathological lesion below that point.

After the operation the patient vomited almost without cessation and steadily grew weaker, but she retained her nutrients well, and by six days she was able to take a little nourishment by mouth. Gradually the vomiting quieted down, and in time she gained strength, appetite, and was discharged six weeks after operation, without symptoms and in fairly good condition.

In September, 1903, she reported that she had gained thirty-five pounds, that she had had occasional vomiting since leaving the hospital, and that in May, after a severe attack of vomiting and strangling, she felt something sticking in her throat, which she vomited up, and which she described as a blood clot the size of a small egg. It probably was the button, which had slipped into the stomach and was thrown up in this way, although the vomitus was not examined at the time. She was more or less sore afterward, as though some metal substance had scraped her esophagus, but since then she had had less dyspepsia and vomiting. About once a month she had some nausea and vomiting, but was able to do her own housework, eating simple food.

In April, 1904, she reported to the Gynecological Department that she still vomited blood at times, but was under treatment for pelvic trouble.

No. LXXIII. Female, twenty years old, referred by Dr. Ferguson in April, 1903.

For two years she had had epigastric pain, coming on after eating, with, at times, vomiting of blood.

A year before I saw her there was pain and vomiting immediately after eating, with epigastric tenderness, and she was obliged to give up her work. At that time she developed tuberculosis of the lungs and was treated accordingly, with considerable relief to her pulmonary trouble. She was unable to eat solid food without severe epigastric pain. There was diminished hydrochloric acid in the stomach contents, and examination suggested functional rather than organic disease. She was anemic and operation was advised more in the way of exploration than with a view to finding any organic lesion.

At operation at the Boothby Hospital, the stomach was found somewhat dilated and there was some induration, but the lumen was normal and along the greater curvature some enlarged lymph nodes were found. The examination of the interior of the stomach showed a slight roughness close to the pylorus that suggested an ulcer or a scar. An anterior button anastomosis was made and the wound closed. The patient was in poor general condition and extensive operation was not permissible. Convalescence was satisfactory and she left the hospital in good condition, relieved of her stomach symptoms.

No. LXXIV. Female, twenty-one years old, had suffered from stomach trouble for five years. Three years ago she had had hemorrhage, preceded by epigastric pain, especially after eating, and at that time she had not only hemorrhages from the stomach, but from the bowels. Was in bed four months, then had more or less retching and vomiting of coffee grounds, the vomiting coming on at once or about an hour after eating. Under the care of a stomach specialist she grew stronger and gained weight, but the conditions recurred about three months before I saw her, and she began vomiting, lost weight, and suffered from pain in the epigastrium after eating, with relief from vomiting. Examination showed tenderness to the left of the median line in the epigastrium. The stomach was apparently contracted. On account of the long duration of her dyspepsia, the hematemesis, chronic invalidism, persistent pain in the epigastrium, and recurrence in spite of long medical treatment, exploration was advised.

At operation, at the Carney Hospital, November, 1903, the stomach was found sagging a little downwards and to the left, but the pylorus appeared free and open. Gall bladder region was negative. No scars nor evidence of ulcers could be seen on the outside of the stomach. A posterior gastro-enterostomy, in the usual way, was done and the abdomen closed in layers. The stomach, at the time of the anastomosis, contained an excess of dark fluid blood, showing recent hemorrhage. Patient steadily gained in weight and strength and was discharged in three weeks, eating ordinary diet.

When seen in May of this year the patient was eating heartily of ordinary food, without trouble except that recently she had had some hiccough and was troubled with constipation. Both of these cleared up under simple remedies.

No. LXXV. Male, seventy-six years old, was seen with Dr. Brown of Newburyport in consultation, in September, 1903.

Three years before he had had a severe universal dermatitis, from which he had been entirely relieved. A year afterwards he began to have symptoms of duodenal ulcer, although for many years he had had indigestion, lasting for a week or more, coming on about two hours after meals, without vomiting, and ceasing on milk diet. In attacks two years and one year ago he had had tarry stools, and in the latter attack was in the hospital on rectal feeding, for three weeks. The pain persisted, however, for some time after discharge, gradually subsiding. For a year he had dieted more or less, and when I saw him there had been fresh blood in the stools for two days. Previous to this the blood had always been digested. For a month he had had quite constantly a mild distress in the stomach, not relieved by milk diet. He was healthy, with slightly atheromatous arteries, and just above the umbilicus a small, slightly tender swelling could be felt. Owing to his age and his success under rectal feeding in his preceding attacks operation was advised against. Two months later, not having gained at all and being obliged to resort to rectal feeding more or less of the time, operation was advised.

At operation, at the Newburyport Hospital, a thickened ulcer of the duodenum just beyond the pylorus was found, with recent adhesions and an appearance of beginning perforation. A posterior gastro-enterostomy, with clamps, in the usual way, was made and the wound closed in layers. The patient made an uneventful recovery, without pain or vomiting, food was taken early, and three weeks later, at Thanksgiving, he was able to eat a complete dinner without distress. Up to the present time the patient remains perfectly well.

No. LXXVI. A woman, forty-three, years old, referred by Dr. Boland.

Patient had had emphysema for several years, and for six months had had severe attacks of abdominal distress, at times so severe that she screamed with pain, being unable to lie down and obliged to sit up on the edge of the bed until exhausted. These attacks came on about midnight, rarely in the daytime, and rarely was there vomiting. The pain and distress were always referred to a point to the right, above the umbilicus. She had lost weight and looked badly. Examination showed absence of liver dullness in the normal situation. Both kidneys were prolapsed. The intestinal coils were plainly visible. So far as could be determined the severe attacks of asthma were caused by the gastric distress. Only partial relief could be obtained from nitrite of amyl. From the fifth rib downward the chest was markedly scaphoid.

During operation, at the Carney Hospital, in December, 1903, the patient was moderately cyanotic throughout, but had no attack of asthma. The liver was found prolapsed, lying entirely below the costal margin, the diaphragm itself lying almost on the level of the lower cartilages and the lower border of the right lobe at the level of the pelvic brim. The stomach, also, was prolapsed, as well as the first portion of the duodenum, but the second and third portions were apparently not depressed. The pylorus was thickened but not indurated, the lumen admitting the tip of the finger. The gall bladder and ducts were normal. A posterior gastro-enterostomy, with clamps and sutures, was made, the mesocolon being found firmly adherent, in places, to the stomach, but no scars were seen.

The patient convalesced satisfactorily from the operation, her asthma disappeared, and in three weeks she was discharged, in good condition. Since then the stomach has caused no trouble but she still has asthmatic attacks.

No. XXVII. Male, thirty-six years old, was picked up, in August, on the railroad tracks, lying in a pool of vomited blood, and was brought to the Carney Hospital at once.

He had been feeling ill for a week and everything he ate caused distress. That morning, before the hemorrhage, he noticed a black stool, and felt weak and unable to go to work. While walking on the railroad track, to his work, he became weak and dizzy and vomited

both food and blood. After admission he vomited blood a number of times, but refused operation. Adrenalin was given and at the end of three weeks he was discharged, relieved, in much better condition.

In December of the same year he returned, begging for operative relief, stating that for three weeks after his discharge he had felt pretty well and was able to work part of the day for a while, but then gave up because of weakness. He had had no vomiting since he left, but had been unable to eat ordinary food, and two weeks before entrance fainted. Examination showed him pale, with a sunken abdomen and soreness in the epigastrium.

At operation a contracted stomach, with open pylorus, was found, without evidence of scars or induration anteriorly. Posteriorly the mesocolon showed scars as from old inflammation and towards the right was adherent to the stomach. A posterior gastro-enterostomy, with clamps and sutures, was made and the abdomen closed in layers.

For two or three days the patient vomited considerable blood and passed blood by stool, but it was controlled by adrenalin, and at the end of three weeks he was discharged, eating solid food, with marked gain in weight and color. Since then the patient has steadily gained and when last seen was as well as ever.

No. LXXVIII. Male, forty-five years old, entered the Carney Hospital in October, 1903.

In August he had epigastric pain and stasis, followed three weeks later by hematemesis. Since then he had spit up small amounts of blood once or twice a week. A few days before he had had a small hemorrhage, without nausea or vomiting, and he described a lump in his stomach from which the blood seemed to come. He had a good appetite, but could not retain his food and was constipated. He had lost twenty-five pounds, but had never noticed blood in the stools. Distress in the stomach came on after eating. Examination of the stomach showed badly digested food, free hydrochloric acid, no blood.

At operation, by Dr. Bottomley, scars and adhesions were found in the posterior wall near the pylorus. A posterior gastro-enterostomy, with clamps and sutures, was made, and the patient was discharged in three weeks, eating solid food without discomfort.

No. LXXIX. Male, sixty-seven years old, referred by Dr. Stubbs of Newton.

The patient had complained of indigestion for two years and had been on medical treatment during that length of time. In the beginning he had had lavage every second day for three weeks. This was followed by some relief for six months, then the symptoms returned and he obtained no relief from a repetition of the washings. Three months before I saw him he had had marked indigestion, without blood in the stools, the distress coming on two or three hours after eating or at times appearing in the middle of the night. It was described as a dull, heavy pain across the middle of the abdomen. Examination of the stomach showed the lower border an inch and a half below the umbilicus.

At operation, at the Carney Hospital, in December, 1903, a moderately dilated stomach was found, and at the pylorus on the duodenal side was a tumor, not indurated like a malignant growth, apparently occluding the lumen and without lymph nodes in the neighborhood. A posterior gastro-enterostomy, with clamps and sutures, was made.

The patient was discharged in about two weeks, eating and enjoying regular food, without having vomited at all, and up to the present time he is perfectly well, without any symptoms.

No. LXXX. Female, twenty-seven years old, referred by Dr. T. J. Murphy.

Two years before I saw her she had had slight hematemesis, which had disappeared under restricted diet. A year ago she had a relapse lasting several months, accompanied by pain. Relief then followed for about five months, when she consulted Dr. Murphy, complaining of sharp epigastric pain not severe enough at the time to suggest a perforation. Under treatment this subsided until two weeks ago, when the pain returned. Four days before I saw her, vomiting began and two days afterwards this became profuse, at first containing dark, later bright blood. For three or four days the stools had been black, and she became blanched, with a rapid pulse. At my visit I found an exsanguinated, sick-looking woman, with definite tenderness in the epigastrium to the right of the median line, and a rapid, thin pulse. Operation was advised at once. She entered the Carney Hospital and we found, at the pylorus, anteriorly and extending into the lesser curvature, an irregular scar an inch and a half in diameter, indurated and crater-like to palpation, evidently the source of bleeding. A posterior gastro-enterostomy, with clamps and sutures, was done as quickly as possible as the patient was in too poor condition to warrant a pylorectomy. The wound was closed in layers.

The patient recovered steadily, with occasional vomiting, which finally subsided, and at the end of a month or so was discharged in good condition. In May she reported in good condition, with slight dyspepsia for a short time, relieved by limiting her meat diet.

No. LXXXI. Female, thirty-nine years old, entered the Carney Hospital January, 1904, with a history of gastric hemorrhage in profuse amount six and four years previously. For ten years she had had more or less severe pain in the stomach and one month ago the pain grew worse and she complained more of the distress after eating, and vomited. She had lost weight and at entrance was pale, with a mass easily felt under the left costal border, moving with respiration.

At operation, by Dr. Bottomley, the pylorus was found open, the stomach was adherent to the liver all along the lesser curvature, and about three inches from the pylorus below the lesser curvature were adhesions between the stomach, liver and abdominal wall, evidently the site of an old ulcer. The gall bladder was adherent to the duodenum by a broad band. To the left and below the stomach the adhesions were numerous. A posterior gastro-enterostomy, with clamps and sutures, was done, a few adhesions of the mesocolon near the pylorus being found.

The patient convalesced satisfactorily, and in three weeks was discharged, in good condition.

No. LXXXII. Male, fifty-eight, entered the Carney Hospital in February, 1904, with history of indigestion sixteen years previously, obliging him to stop work after two years.

Since then he had had a more or less sore stomach. For two years he had had spells of feeling pretty well, but as a rule, three hours after eating, he had violent pain in the stomach, relieved by enforced vomiting. The vomitus was excessive in amount, of a slimy fluid and very acid. Examination showed sclerotic arteries, a distended stomach filling the abdomen, with a capacity of over five quarts. There was general ptosis as well. At operation by Dr. Bottomley the pylorus was found normal, but surrounded by many adhesions. The gall bladder was normal but adherent to the omentum. The adhesions were freed and a posterior gastro-enterostomy, with clamps and sutures, was made.

The patient rapidly convalesced and in three weeks

was discharged, eating solid food without pain or distress and with relish.

Examination of the stomach contents before operation showed presence of hydrochloric acid.

No. LXXXIII. Female, twenty-five, had been well up to three weeks before entrance to the Carney Hospital, when she had pain in the stomach, with vomiting. For a week she was nauseated but did not vomit, then she went to bed, with a severe epigastric pain, vomiting, and much tenderness to pressure on the abdomen. Since then there had been much sharp pain in the epigastrium, relieved somewhat on lying down. She had not eaten solids for a week, but was able to take liquids.

Examination showed an anemic girl, tender in the epigastrium, with slight spasm over the pylorus. Operation showed at the pylorus numerous old adhesions to the colon and omentum, extending from an irregular scar on the anterior wall of the pylorus, both on the stomach and duodenal side. Close to the pylorus on the proximal side was a pouching of the stomach, with a slight contraction as in a beginning hour-glass stomach. The stomach was not dilated and the pylorus was open, although contracted to about half its normal diameter. The duodenum was mobilized and a gastro-duodenostomy was made by Finney's method and the wound closed.

For a day or two the patient had more or less vomiting, which then ceased, and she steadily gained, eating solid food without distress, and was discharged in two weeks, in excellent condition.

No. LXXXIV. Female, thirty-two years old, was referred by Dr. Hamblen of Maynard.

For three years the patient had been unable to work at her business as a dressmaker. The trouble started with a so-called attack of grippe, which lasted three months and from which she had never recovered, being in bed for several weeks at a time, off and on. She had been unable to take solid food from the first and had been troubled more or less with gas. In some of her attacks she would vomit, but after going to bed and living on liquids the trouble would stop, only to return after eating ordinary food. For over a year she had not eaten a good square meal, and had lost over twenty pounds. The pain would come about half an hour after eating, was worse when lying down, and would last until she vomited, with relief at once. She had vomited retained food and in excessive amount. The distress varied somewhat and was relieved at times by the various medicines for indigestion. She had been very constipated. Examination showed a slightly distended stomach with free hydrochloric acid, and poorly digested food. The lower edge of the stomach was an inch and a half below the umbilicus.

At operation at the Carney Hospital the stomach was found dilated, the upper edge being about an inch above the umbilicus. From the gall bladder a broad sheet of adhesions, thickened anteriorly into a stout band, passed to the anterior wall of the stomach to the proximal side of the pylorus. In addition there were diffuse adhesions over the duodenum. Most of these adhesions were separated and ligated. The pylorus was contracted spasmodically, but admitted the tip of the finger. There were no signs of ulcer. A posterior gastro-enterostomy, with clamps and sutures, was made. Posteriorly, near the pylorus, were some scar-like bands. The gastrohepatic ligament was shortened with catgut and the abdominal wound closed in layers.

The patient convalesced rapidly and was discharged in three weeks, eating solid food, and has remained perfectly well ever since.

(To be continued.)

Medical Progress.

REPORT ON DERMATOLOGY.

BY JOHN T. BOWEN, M.D., BOSTON.

ETIOLOGY OF ALOPECIA AREATA.[1]

THIS subject was brought up in the French Society of Dermatology at the meeting in May, 1904. M. Jacquet, who is well known as an exponent of the theory that many cases of alopecia areata are connected with dental lesions, showed a patient who had suffered since 1902 with alopecia areata of the moustache on the left side. The lesion had started shortly after a severe pain in the teeth of the left side which necessitated the extraction of two molar teeth. There was also hyperesthesia of the left side of the face. The extraction of the teeth arrested the disease. The hair began to grow in, then stopped. The hyperesthesia and increase of temperature on the left side of the face continuing, Jacquet suspected that there remained a remnant of root or bone not eliminated. In point of fact, a small fistulous opening was found which was curetted under chloroform and exposed the extremity of the posterior outer root of the first large superior molar tooth.

During the eight following days, hair continued to fall very quickly, after which it began to grow in so rapidly that in five weeks the area was entirely covered; also the increased sensibility and increase of temperature disappeared immediately after the operation. The hairs, however, did not grow in vigorously, and the recovery could not be considered complete.

In sum, we have here a case of alopecia areata in which the permanence of troubles of sensation made it easy to diagnosticate the presence of an important bit of stump, and where the alternations of alopecia and of regrowth were associated with fluctuations of the deep lesions.

In the discussion, Darier said that since his attention had been drawn by Jacquet to the possible relationship of alopecia areata with dental lesions and other nervous troubles, he had always examined into the state of the teeth in such cases, and had been struck with the fact that in the large majority of cases dental lesions were found, of different varieties, but capable of causing nervous excitement. When there is a lack of dental lesions, there are often symptoms in the region of the trifacial nerve, or vasomotor disturbance. He admits, however, that in some of the cases all such conditions were absolutely wanting.

Brocq also asserted that he had observed an intimate relationship between the appearance of wisdom teeth and certain alopecia areatas. He took occasion to speak of the present rule according to which subjects of the disease under discussion are not allowed in offices and workshops. This is oftentimes a great hardship, particularly in view of the fact that there is no unanimity as to the question of the contagiousness of alopecia areata. For this reason, he proposed the

[1] Ann. de Dermat. et Syph., May, 1904.

appointment of a committee to examine carefully into all the new facts regarding contagiousness and epidemics.

At the same meeting MM. Gauchet and Lacapére presented to the society four cases of alopecia areata which appeared to have been produced by contagiousness. They bear upon the observations of epidemics of alopecia areata in schools and in barracks. Although thinking it probable that many of these had not been accurately studied, in the four cases reported, the diagnosis had been made by different dermatologists of the St. Louis Hospital.

The patient who first appeared was a member of the police force, who had been affected at the same time, or a little after, three other men who belonged to the same squad. These four men were in constant relationship with one another. Every other day they were on guard at the prefecture of police. In the intervals of these duties these men were accustomed to lie down upon the same bed.

Four months ago, one of them saw that his hair was falling. This man was twenty-eight years of age, had been subjected for some time previously to considerable anxiety, and it was soon after the termination of this that there appeared on the right side of the head a small patch of alopecia areata, the size of a fifty-centime piece. Two or three weeks later, two new plaques appeared at the occiput, and a month later the beard and moustache were affected.

About a month after the beginning of this case, the second case appeared in a man of the same squad. He exhibited a small patch on the apex, which rapidly improved under treatment.

Two months after the beginning of the first case, a third man, colleague and neighbor of the first two, developed a small patch of alopecia areata in the beard. This man had had a previous attack of alopecia nine years before, for which he was treated at the hospital.

The fourth case, that of the one who called attention to this little epidemic, had been affected for only five or six days. Eleven years previously he had had a similar lesion.

The conclusion is reached that it is impossible to attribute these four cases to any other cause than that of contagion.

Several of the members asserted that it was their custom to give certificates to persons affected with alopecia areata to the effect that the disease was only contagious by direct contact; and that a person could be received at a workshop or office provided the head was kept constantly covered.

Hallopeau asserted that people who constantly have their head covered do not generally have alopecia areata. None of the Sisters of Charity are affected in the hospitals, while members of the medical corps are not infrequently affected.

At the conclusion of the discussion, a commission was appointed to examine thoroughly into the question of the contagiousness of alopecia areata.

LEPROSY IN BRITISH GUIANA.[2]

British Guiana is a territory which comprises an area of one hundred thousand square miles. The population is about three hundred thousand, of which one third are East Indians, about ten thousand aboriginal Indians, and the remainder Europeans, Portuguese, Chinese and negroes. It is believed that leprosy was introduced by negro slaves from Africa in the period of slavery. The only Indian tribe in Guiana that has been affected with leprosy is the Warraws. In an official report made in 1878, the writer gave a table showing an increase of 160% of cases of leprosy during the twenty years between 1858 and 1878, during which time 1,120 cases of leprosy were dealt with in the asylums. Of these 657 were negroes. The largest number of cases came from the parish which is situated in one of the healthiest parts of the country, so that the excess in the number of cases here could only be explained by the free communication with the surrounding neighborhood that was allowed these people.

The types of disease met with were similar to those in most tropical countries. Twenty-one per cent were of the tubercular type, 62% nerve leprosy, and 17% were mixed cases. About one in every two hundred and fifty of the inhabitants of Guiana suffered from some form of leprosy.

This paper is intended as a plea for leper asylums for these unfortunate people. Something has been done in Guiana in the line of improving the asylums, but they are still far from good. The writer thinks that cases of nerve leprosy should be dealt with much less strictly than cases of tubercular leprosy, and that every case of the latter type should be placed in a properly constructed asylum unless satisfactory arrangements can be made for home treatment and isolation.

PAGET'S DISEASE OF THE UMBILICUS.[3]

The patient, who was shown on two separate occasions to the London Dermatological Society, was a sailor, sixty-five years of age. He had been previously well, with no family history of cancer. He exhibited in the umbilical region a round exanthematoid patch about two inches in diameter which had been gradually forming for about eleven years. The central part was ulcerated and exuding, covered over in parts by epithelium. There was a raised broad border, over which the cuticle was intact. There was considerable infiltration. The case proving rebellious to treatment, a bit of tissue was excised, which showed it to be an example of Paget's disease. The diseased skin was then removed surgically.

Histologically, there was great proliferation of the epidermis, the interpapillary processes extending deeply downward, but ending at about the same level in the corium. The cell inclusions, which were erroneously described by Darier as coccidia, were present throughout the epidermis. The corium was densely infiltrated with cells, which were especially numerous about the blood

[2] J. D. Hillis. Lepra. Vol. IV, fasc. 2. 1904.
[3] Brit. Jour. of Dermat. Feb., 1904. Fox and Macleod.

vessels. These were generally plasma cells, with a few leucocytes and connective tissue nuclei. The writers then presented a very good résumé of the literature of Paget's disease. It was in 1889 that Darier first noticed the remarkable changes which accompany the proliferation of the epithelium. He believed the peculiar bodies found in the epithelium to be coccidia, and the cause of all the trouble. All of the earliest cases affected the nipple so that the name of Paget's disease of the nipple became the customary one. In this situation it is diagnosticated by the age of the patient, mostly between forty and sixty, by its chronicity and slow progression; and it is distinguished from ordinary eczema by its bright red color, hard, raised border, and islands of epithelium in the diseased area. The precocious retraction of the nipple is also a marked feature.

Darier states that he has seen a dozen cases of epithelioma elsewhere than on the breast, with slow progression, well-defined borders, slight induration of the surface, and sometimes ulceration, which clinically differed very little from Paget's disease.

In 1889, Radcliffe Crocker described a case of a man of sixty who presented the disease at the root of the penis and scrotum; it spread rapidly over the whole of the left half of the scrotum, reaching the pubes. Other cases have been observed in France and England where the affection was situated about the anus and pubes, also about the female genitals. A case in this situation has also been reported by Fordyce in this country.

Remarking on the histology of the case reported, the writers conclude that the microscopic appearances were identical with those found in the typical cases situated on the nipple. There was no evidence of definite malignant change in the epidermis. They did not believe, as has been asserted, that the peculiar change in the epidermis is malignant from the first, any more than that ordinary warts or pigmented nevi are all malignant from the first. They may all be described as pre-cancerous lesions of the skin, which have a tendency to become malignant.

In this case a portion of Meckel's diverticulum was included in the center of the umbilicus, which may have been a coincidence, although it is a suggestive one.

The general histological appearances suggest chronic inflammatory disturbance, involving the papilli and leading to proliferation, edema, and degeneration of the epidermal cells and the formation of a resistant cellular infiltration in the upper layers of the corium.

The writers can throw no light upon the important question of the actual cause of this precancerous dermatitis and subsequent carcinoma. Although Darier's theory that the degenerated cells were coccidia and caused the disease has been abandoned by all, including its author, a parasitic origin would fit in very well with the clinical appearances and course of the disease.

Jungmann and Politzer,[4] in a very recent article, report a case of Paget's disease in which the axilla was the starting point of the process, and the nipple was not affected until thirteen years later. The woman was forty-six years old when the affection began in the left axilla as a small, red, oozing spot which greatly increased in circumference until, four years later, it had reached the size of the palm of a child's hand. At this time, she was seen at the Vienna Hospital, where the diagnosis was that of eczema. A long course of treatment had no effect upon the disease.

When taken into the hospital a second time, in 1903, the affected area extended on the left side of the chest from the axillary hollow as a center, on one side over the anterior half of the thorax, on the other side, behind, as far as the region of the scapular. It was also present on the inner surface of the upper arm. In the central, excoriated portion of the affected tissue, a hard infiltration of the deeper tissues was observed, and a fungous, ulcerated tumor of the size of a fig was situated on the anterior axillary fold. There was also a large nodule on the upper arm. The arm was lifted from the chest with so great difficulty that it was impossible to determine whether or not the deeper glands were affected.

On account of the favorable action of the x-rays on cancer of the skin, the patient was put under this treatment and with most gratifying results. After two or three weeks, there was a reaction of the first grade, after the subsidence of which the skin began to heal and the tumors to undergo involution. The general condition, also, improved continuously. At the time of writing, the parts were covered with solid epithelium and the tumors had practically disappeared.

Histologically, the appearances were those that have been shown to be characteristic of Paget's disease, and included the peculiar cell inclusions which have been described as coccidia.

The authors rightly protest against the retention of the name "Paget's disease of the nipple," inasmuch as the affection has been found in so many other localities.

[4] Dermat. Zeitsch., June, 1904.

RADIUM IN CUTANEOUS AFFECTIONS.

At a meeting of the Berlin Medical Association on May 4, of the current year,[5] Lassar demonstrated patients and showed lantern slides illustrating the therapeutic action of radium. He said that during the last half year, he had treated a number of patients in this way, especially those afflicted with superficial tumors. It was demonstrated that this method of treatment was entirely harmless. When patients were daily treated for half an hour with one milligram of radium in small capsules bound down to the part treated by plaster, no inflammatory or necrotic results were produced. Numerous patients and pictures were shown illustrating the effect of this treatment on epitheliomata of the face. One case had been treated without success by various other methods and entirely healed by radium. It has been clearly shown that it is chiefly new

[5] *Ibid.*

growths that are healed by radium; and its great advantage over other similar methods is its easy application by an unskilled person. The cost is still high, but much less than that of the Röntgen apparatus, which requires also the services of attendants, etc. It also has a great advantage in that it is inexhaustible.

In regard to disagreeable occurrences, if there is the slightest sign of inflammation, redness, or swelling, the procedure should be interrupted. It is most important, however, that the physician should keep a personal supervision.

Other cutaneous affections were tried by this method. A case of obstinate, long continued psoriasis was completely relieved. The author is also able to record some favorable results in carcinoma of the breast. Naturally, this treatment does not take the place of surgery, and is applicable only to superficial lesions. Recurrent cancers may be satisfactorily treated in this way.

LARVA MIGRANS.[6]

Lengtel and Delaunay reported the following interesting case which they saw at the Hôpital Broca. It occurred in a man thirty-nine years of age who had had, three weeks previously, a furuncle of the outer part of the calf. He treated it by a remedy of his own composition, namely, a poultice made from a dozen living snails, which he procured at the market. Shortly after this the furrows appeared.

When seen, he presented on the right part of the calf a plaque of lymphangitis as large as the palm of the hand, which bore in its center the scar of the original furuncle. Over this plaque were there numerous tunnels like enormous scabietic burrows, of reddish color at the border, white at the center, and flooded with sero-purulent matter which was collected here and there in droplets. These tunnels or galleries were irregular and tortuous. There was some intermittent pruritus. All attempts to find the parasite were vain, in spite of repeated examinations.

Histologically, the tunnel is seen situated in the upper layers of the rete, which is never destroyed in its lowest layers. The horny layer was almost intact, simply elevated by the exudation which filled the furrow. Parallel to the large furrow were numerous very small secondary furrows whose lumen opened into the central furrow. The writers conclude that the affection has all the appearances of a parasitic disease, and the eosinophilia which they observed about the furrows tended to confirm this theory. It is probable that the parasite, which they were unable to detect, is very small. The tunnel seems to be the effect of a process of digestion, a late reaction of epithelial tissue to the toxins, or dejections left by the larva. There is little in medical literature upon this subject, and no agreement in the results of different dermatologists. The disease is said to have been observed frequently in Russia, especially in the eastern part. There the parasite is thought to be of large size. The affection was named hyponomoderma by Kaposi. Lee described it as a creeping eruption, while Crocker and Stelwagon named it larva migrans. In Lee, Crocker and Stelwagon's cases, the parasite could not be found.

Some authors consider that the parasite is a larva of gastrophilus, which is transmissible from herds to man. Neumann, who was unable to find the parasite itself, thinks that it is due to an acarus. In the case described, it is assumed that the snails were the vehicle of infection.

On the whole, the parasite has never been found except by Russian authors. In other countries the most careful search has been unable to detect them. The patient was treated with applications of tincture of iodine, at first upon the central part. During this time the furrows at the periphery continued to increase, but no new tunnel started from the center. The applications of iodine were then extended to the whole of the affected territory, and under this treatment the patient rapidly got well, which they regarded as a proof of the superficiality of the parasite.

Reports of Societies.

AMERICAN SURGICAL ASSOCIATION.

PROCEEDINGS OF THE TWENTY-FIFTH ANNUAL MEETING, HELD IN ST. LOUIS, JUNE 14, 15, 16 AND 17, 1904.

(Concluded from No. 7, p. 194.)

A MECHANICAL DEVICE FOR GASTRIC AND INTESTINAL ANASTOMOSIS.

DR. F. B. HARRINGTON of Boston described a ring for the purpose of intestinal anastomosis.

The advantages of this ring were stated as follows:

"1. Safety and speed. A complete resection and suture can be easily done in fifteen minutes, and with as great speed as by any more protracted method.

"2. Cleanliness. Assisted by clamps, the purse-string sutures prevent even a mucous ooze, while the continuous stitch is being placed.

"3. The intestinal suture is more easily done over the ring than without it.

"4. It is safe to use a single layer of continuous stitches, since the ring allows a perfect approximation to be made, and afterwards protects the suture until adhesions have formed.

"5. The handle is very useful for holding the intestines in convenient positions for sutures.

"6. It is not necessary to sew up any of the layers, since a study of specimens from animals and human beings shows that the mucous membrane will slough in any case, and that repair is more rapid when the mucous membrane is not sutured.

"7. The presence of the ring guarantees a free opening at the site of operation.

"8. In case the continuous stitch should be improperly applied, the weak spots are protected by the ring itself, for at least three days, until the ring breaks down. This allows strong adhesions to form.

"9. After operation the ring holds the suture immovable, and acts like a splint. The weights of the individual segments of the ring vary, as most other appliances of a similar nature."

Conclusions. — The author drew the following conclusions:

"1. The process of repair is as rapid after the use of the segmented ring as after a plain suture.

"2. The time required for the operation is, on the whole, less than that required for a straight intestinal suture.

"3. Certain objections, such as weight, ulcer, difficulty of passage, etc., inherent in other mechanical contrivances, are minimized by the ring.

"4. The analogy between the experimental and human observations is so close as to show the propriety of the deductions made from animal experiments.

"5. The employment of the ring in human beings is safe and satisfactory."

In the discussion of Dr. Harrington's paper, DR. J. W. DRAPER MAURY of New York City, by invitation, stated that instead of using the elastic ligature at the laboratory of Columbia University, they had been employing twine. The specimen which he exhibited was made with the elastic ligature, put in by a square knot, thus differing from Dr. McGraw's technic; but for the last three months he had obtained as good results by using simple twine instead of the elastic ligature.

The method of introducing the twine might follow the McGraw technic, although the triangular stitch possessed a very distinct advantage over it. This stitch punched out as much tissue as might have been included in the triangle. As to time, it would cut through in less than three and a half days. It must be very tightly tied. This was the sole requirement to success.

Dr. Maury then demonstrated on a chart the technic of introducing the triangular stitch, and stated that he included about one third the circumference of the gut in the stitch. The gastric triangle should, as a rule, be made larger than the intestinal.

He then passed around photographs of specimens made by this method, and a preparation from the gut of a pig, which demonstrated how free an anastomosis might be established. He also showed a number of circular bits of twine, which had been used in executing the technic. They had cut the triangle out and had been recovered after their passage through the rectum.

THE SUBTLE FORCE OF RADIUM.

DR. ROBERT ABBE of New York City narrated his experience with this new therapeutic agent, saying that radium had a powerful and seemingly beneficial effect upon cases of recurrent carcinoma. Cases were cited in point. He mentioned one case of virulent, typical carcinoma of the scirrhus type, in which the carcinomatous nodules were reduced to one third their original size by radiomization. The agent had been used in cases of lupus, superficial epitheliomata, carcinoma, rodent ulcer, superficial sarcomas, etc. In cases of superficial recurrent carcinoma of the breast, if radium was applied to the diseased area for a considerable time, say an hour, then the patient permitted to go, and the agent reapplied at intervals of two or three days, the carcinomatous masses would melt away in some cases. In other instances these masses would disappear under the use of the x-ray, still others would resist the action of the x-ray, while radium would act beneficially. Radium had an extraordinary power in inhibiting the growth of malignant cells in some cases.

DR. W. W. KEEN of Philadelphia said that one positive fact was worth a dozen negative ones. One could not get away from the facts presented by Dr. Abbe and others in regard to the use of radium. On the other hand, members of the profession ought to report their negative as well as positive results. He had had an experience now covering twenty-two cases in which radium was used. Whether his results were due to the quality of radium, to a difference in the character of the growths, to the method of using it, or what not, he did not know. But to sum up his experience, in not one single case had there been the slightest benefit, except in one feature, and that was as to pain. Unquestionably, in cases of carcinoma, patients had suffered less, and in a large number pain had disappeared. In one case of tic-douloureux of the lower jaw the man left the hospital at the end of a month practically well. In the course of six or eight weeks the patient wrote him that he had had a recurrence of the pain. Dr. Keen wrote him to return for treatment, but had heard nothing from him since, and whether the pain had disappeared or not, he did not know. He had used the German instead of the French radium. Some of his specimens had varied from 17,000 radio-activity up to a larger radio-activity, until finally he was able to obtain one specimen with 1,800,000 radio-activity. He regretted to say that his experience had not been satisfactory with the use of radium.

GASTROSTOMY IN ESOPHAGEAL STRICTURE.

DR. JAMES H. DUNN of Minneapolis, Minn., said that cicatricial stricture was the most serious benign affection of the esophagus. Retrograde and through and through treatment of certain esophageal strictures had been recognized since the operation of Loretta, in 1883; but discoveries and improvements in operative technic had finally completely changed the situation, leaving surgeons in a position to approach one of these cases with a very safe and certain technic, and to fill the following indications: (1) A gastric fistula which would not leak, and close spontaneously. (2) To get a reliable guide through the canal with perfect safety and certainty. (3) To divide the scar tissue sufficiently. (4) Relative asepsis and rest of the wounded surface, prevention of stagnation of food, and for a time the irritation of its passage.

The value of the Stamm-Keder form of gastrostomy was generally understood, but it was only when one fully appreciated by experience that any esophageal stricture might be commanded perfectly and with precision by means now at hand, through very small gastric fistulæ, even the size of a No. 20 French catheter or less, that all the advantages of the method appeared. The steps of the operation were described. A modification of Dunham's wire and spindle bougies was suggested as somewhat simpler and more handy. The writer had not found it necessary to use guards to protect the epiglottis and stomach fistula from chafing. By this plan but one anesthesia was necessary in each case. The fistulæ had not leaked and had promptly healed spontaneously. A caliber admitting of free swallowing was reached in from one to three weeks, and an approximately normal caliber achieved in from two to four months, after which the tendency to relax had been imperceptible. The author reported three very severe cases, one in a girl, aged nineteen, following typhoid ulceration, and two in children, aged nine and two years, from the ingestion of concentrated lye. Repeated attempts had failed to reach the stomach through the mouth in all these cases.

SURGERY OF NERVES; THE BRIDGING OF NERVE DEFECTS.

DR. CHAS. A. POWERS of Denver, Colo., said the difficulties in the way of preparing a satisfactory paper on this subject were due to the indefinite manner in which nerve suture was treated in medical literature, to the widely scattered and badly indexed material

collected and published by Chipault, to the fact that much of the material in the literature of the subject described operations upon animals, that a large proportion of operative cases in men were reported before the establishment of a permanent result, and to the fact that in case of failure it was not easy to say that a given bad result was due to a faulty technic in the operation itself as a similar result might have followed direct suture of the fragments.

The author reported in detail a personal case of transplantation of four inches of the great sciatic of a dog to the external popliteal of a man. Union was prompt. The fragments stayed in place, and the immediate result seemed to be encouraging, but the ultimate result was a total failure. Examination and report were made eight years after operation.

Cases of the bridging of nerve defects gathered from literature showed the following number: Grafting, 22; flap operations, 11; implantations (anastomosis), 10; resection of bone, 7; *suture a distance*, 3; tubulization, 1.

Analysis of these cases showed that grafting was a failure and should be discarded, while the results in flap operations and anastomosis were about the same, something over 50% of the cases being successful. While these last operations were not very promising, they seemed at present to be the methods of choice.

FINAL RESULTS IN SECONDARY SUTURE OF NERVES.

DR. EMMET RIXFORD of San Francisco, Cal., reported three cases of secondary nerve suture, of the ulnar at the wrist, of the musculo-spiral and the facial at the stylo-mastoid foramen, six, four and two years, respectively, after operation. In the first case the atrophic thenar, hypothenar and interosseous muscles regained their normal volume and function, save in so far as motion of the fingers was limited by adhesions, the result of fixation and chronic arthritis. In the second case the musculo-spiral nerve was sutured eight weeks after rupture complicating a fracture of the humerus. A defect of three centimeters was overcome by shortening the humerus that amount, and the result after four years was complete motor and sensory restoration of function, with slight atrophy, one-half centimeter difference in circumference in the forearms. In the third case the facial nerve was severed by a narrow tooth beneath the mastoid process. Complete facial paralysis. Suture at eight weeks after the injury. In order to secure tissue for the sutures, the mastoid process was cut away with the surgical engine, and the external wall of the Fallopian canal removed for five or six millimeters. Result after two years: Face symmetrical, when in repose; eye closes in sleep; may be closed at will; angle of mouth, tip of nose and chin can be drawn to the paralyzed side.

The prognosis in secondary suture was but little, if at all, inferior to the prognosis in primary suture. In the presence of infection, secondary suture was preferable to primary.

All scar tissue should be removed, including the whole of terminal neuroma of central segment, the nerve ends united by absorbable suture with the least possible traumatism. Defects, if not too great, could be overcome by stretching, which should be done before section of the nerve ends, or by shortening of the bone in certain cases.

PRIMARY CARCINOMA OF THE LIVER.

DR. LEONARD FREEMAN of Denver, Colo., reported a case of primary carcinoma of the liver on which he had operated, with freedom from recurrence at the end of sixteen months. After dealing with the different methods of operating, he reported his case in detail.

THYROIDECTOMY FOR EXOPHTHALMIC GOITRE, WITH REPORT OF 40 CASES FROM 128 OPERATIONS UPON THE THYROID.

DR. CHARLES H. MAYO of Rochester, Minn., in a paper with this title, said the subject of goitre was still unsettled, both as regards etiology and treatment, although hundreds of articles had been written upon it. Recent investigations concerning the lymphatic system and ductless glands rendered the subject very interesting at this time. Exophthalmic goitre was a distinct type, with many symptoms, involving the mental, muscular, digestive and circulatory functions, the most common being the tachycardia without other cause. While the mortality was comparatively high, it was among those cases which had already run the gauntlet of most known remedies for the disease, and should not be entirely laid at the surgeon's door.

The surgical methods were exothyropexy, ligation of the thyroid arteries, removal of the cervical sympathetic ganglia, thyroidectomy, and the physiological effect of operations upon other regions.

The author and his brother had operated upon 130 goitres; 40 were of the exophthalmic type, and of these, 6 died as the result of the operation. In the first 15 there were 4 deaths due to lack of judgment in accepting almost moribund cases. There were but 2 deaths in the last 25 cases.

Very severe cases were subjected to x-ray exposures, and with belladonna given internally for a few days or weeks previous to operation.

Their own cases showed marked improvement in all who survived the operation. Of these, 50% made a very early recovery, especially of the severe symptoms, such as tachycardia, nervousness and tremor; 25% did so after several months, and 25% were improved, yet suffered from irregular recurrence of some of the major symptoms.

GALLSTONES IN THE COMMON BILE DUCT.

DR. S. H. WEEKS of Portland, Me., read a paper on this subject, in which he considered the diagnosis and prognosis, and said that impaction of a gallstone in the common duct rarely caused marked distention of the gall bladder; it caused dilatation of the branches of the hepatic duct, and might result in pronounced and even fatal jaundice. Obstruction of the common duct was always accompanied by jaundice. The jaundice was intermittent or remittent where the calculus floated in an enlargement of the common duct, because the system would eliminate the coloring matter of the bile in the interval. The cystic duct might be occluded and give rise to grave symptoms without there being any trace of jaundice or any history of biliary colic. Jaundice with distended gall bladder not due to gallstones was presumptive evidence of malignant disease. Jaundice without distended gall bladder favored the diagnosis of cholelithiasis.

As to treatment, it was necessarily surgical.

DR. A. F. JONAS of Omaha, Neb., read a paper on "Primary Splenomegaly, Accessory Spleens, Splenectomy," and reported an interesting case.

DR. S. J. MIXTER of Boston reported a case in which he removed the upper jaw for extensive osteosarcoma, with an excellent result, considering the formidableness of the operation.

DR. RUDOLPH MATAS of New Orleans, La., exhibited and described a new interdental splint which he had recently devised for the treatment of fractures of the jaw, particularly the lower jaw, without bandages.

DR. ALEXANDER HUGH FERGUSON of Chicago exhibited a patient upon whom he had performed renal decapsulation for chronic interstitial nephritis three and a half months ago, with an excellent result.

OFFICERS.

The following officers were elected: President, Dr. George Ben Johnston of Richmond, Va.; vice-presidents, Dr. Emmet Rixford of San Francisco, Cal., and Dr. James Bell of Montreal; secretary, Dr. Dudley P. Allen of Cleveland, O.; treasurer, Dr. George R. Fowler of Brooklyn, N. Y.; recorder, Dr. Richard H. Harte of Philadelphia; councillor, Dr. N. P. Dandridge of Cincinnati, O.

San Francisco, Cal., was selected as the place for holding the next meeting, the date to be decided by the officers and committee of arrangements.

ORGANIZATION MEETING; NATIONAL ASSOCIATION FOR STUDY AND PREVENTION OF TUBERCULOSIS, HELD JUNE 6, 1904, AT ATLANTIC CITY, N. J.

DR. WILLIAM OSLER called the meeting to order at 8.30 P.M. Fully two hundred persons were present. Dr. Osler spoke of the need of an organization that was representative of the medical profession, stated the steps that had been taken and asked Dr. E. L. Trudeau to read the constitution and by-laws as prepared and printed by the committee. Dr. Trudeau was greeted with much applause. Dr. Sternberg moved the adoption of the articles as read. Dr. J. Solis Cohen moved an amendment, so that changes in the by-laws might be proposed by the Association as well as by the Board of Directors. After discussion and acceptance of this and several minor changes, the constitution and by-laws were adopted.

Dr. Trudeau, in presenting the list of directors, said that they had been chosen in proportion to the number of men in each state actively interested in the subject. The following list was unanimously adopted:

Massachusetts, E. O. Otis, V. Y. Bowditch; Connecticut, Foster; New York, Knopf, H. M. Biggs, E. L. Trudeau, Mr. Devine; Pennsylvania, Flick, Ravenel, Anders, Pearson; New Jersey, Mr. Hoffman; Maryland, W. H. Welch, William Osler, H. B. Jacobs, Fulton; District of Columbia, G. M. Sternberg; North Carolina, Minor; Colorado, Solly; Illinois, Klebs, Babcock; Minnesota, Bracken; Missouri, Porter; Indiana, Hurty; Michigan, Vaughan; Ohio, Probst; California, Bridge; Texas, M. M. Smith. Public Health and Marine Hospital Service, Surgeon General Wyman; U. S. Army, Bushnell, Fort Bayard.

Dr. Osler opened an informal discussion of different aspects of the work by suggesting that meetings be divided into three sections: sociological, clinical, pathological and bacteriological. Dr. Barry, Louisiana, made an earnest plea for special attention to the study of tuberculosis among the negroes. He said that the disease had made alarming progress among them during the last ten years. Where the population was equally divided, the doctor would see twenty cases among the negroes to one among the whites.

Another suggestion was a Committee on Publicity to help on the education of the people in regard to tuberculosis through the lay press in addition to a special journal.

Mr. Devine of New York, editor of *Charities*, in a very earnest address spoke of the significance of the awakening of the lay mind to medical problems. He suggested that the Association needs first of all an efficient executive secretary. Practical articles were needed to educate physicians in regard to the details of management. Dr. Wells of Chicago said that tuberculosis is diminishing. That first the people must be reached through the lay press; second, the school teachers must be specially instructed, and third, the medical profession must be aroused to the importance of preventive measures.

DR. TRUDEAU was greeted by prolonged applause. He said that the dispensaries must give the patients directions and spit-cups; that hospitals were needed for the hopeless cases, as well as for the curable. He would have lectures given to physicians on the importance of early diagnosis; that the disease begins long before the bacilli are coughed up in the sputum. He spoke with feeling and gratitude of the increased interest in the subject since he first began alone in the mountains thirty years ago.

DR. HERMAN M. BIGGS of the New York Board of Health said that there were now in New York six special dispensaries for tuberculosis, with twenty-five trained nurses visiting among the patients. There were 1,600 beds available for advanced cases. The Board had recently provided several pavilions for cases removed by force, or vicious and insubordinate cases discharged from other institutions. About 400 cases are reported each week, and 16,000 in a year. If they are attended by a private physician, they are simply registered, and the physician is asked at the end of the year whether they are still under observation. Severe cases are visited by a nurse three or four times a month. Efforts are made to stimulate early diagnosis. The free examination of sputum has been a great help in this respect. When first established, only 400 specimens were sent in during a year. Recently on one day there were 178 specimens sent in. The death-rate in the last seventeen years has been reduced 40%, and in the next ten years it should be reduced at least 40% more.

DR. KNOPF said that no community is too small to have a committee on prevention of tuberculosis, consisting of physicians and interested laymen.

DR. HICKLING of Washington told of the organization of lectures in the public schools, at mothers' meetings, in kindergartens, and, through the Associated Charities, in various church parlors. Usually there were three ten-minute addresses at each meeting, one illustrated.

DR. HUBER of New York spoke of a journal for the Association, and on motion it was voted that "the sense of this gathering is that such a journal should be established."

A meeting of the directors was called immediately after adjournment.

Recent Literature.

A Guide to the Clinical Examination of the Blood for Diagnostic Purposes. By RICHARD C. CABOT, M.D. With colored plates and engravings. Fifth Revised Edition. pp. 549. New York: William Wood & Co. 1904.

This latest edition of Dr. Cabot's well-known book is fully up to the standard of the previous editions. An extended review can only be a repetition of those of the past. As stated in the preface, about ninety pages of new matter have been added and about twenty pages stricken out. The most important changes are due to the introduction of the "Romanowsky" staining method for routine blood examination. A new set of colored plates prepared from specimens stained in this way has been added. Considerable additions have been made to the chapters on Infectious Diseases and Blood Parasites, and minor changes on almost every page in the book.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 25, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 Bromfield Street, Boston, Mass.

DR. OSLER AND OXFORD UNIVERSITY.

The announcement of the appointment of Dr. William Osler to the Regius professorship of medicine in Oxford University has been succeeded by the not unexpected news of his acceptance of the position, although his connection with the Johns Hopkins University will not be severed for nearly a year. Dr. Osler has for many years occupied a somewhat unique position in American medicine. Born a Canadian, a student of medicine at McGill University in Montreal and at Toronto, later a teacher in medicine at McGill University, and pathologist to the Montreal General Hospital, then elected to the chair of clinical medicine at the University of Pennsylvania, and finally to the chair of medicine in the Johns Hopkins University, he has had an experience as a teacher of medicine to which few attain. Well knowing his fondness for the country of his birth and all things English, he had so long identified himself with the United States, that it was with considerable surprise that we learned of his intention to end his immediate connection with this country, even for so tempting a field as that which now opens before him. Not only the Johns Hopkins University but the entire medical profession in America may well feel a certain pride in this choice for the Regius professorship at Oxford. That Dr. Osler is fitted by training and education for the position no one can gainsay. It is as little open to question that he brings to it a peculiar charm of manner, breadth of culture and broad-minded attitude toward medical problems which it would have been difficult to have found associated in any other single individual.

Experience no doubt has taught the Johns Hopkins Medical School to accept with equanimity changes in its faculty. Few institutions have provided men of capacity for positions of trust more widely than she. The departure within comparatively recent years of Councilman, Flexner, Barker and many others for other fields of work must have left places difficult to fill, but the going of Dr. Osler takes from the university one of the two men who have long stood in the very forefront of medical progress in this country, and means a loss which in the ordinary course of events can never be compensated.

It is interesting also to note the vast difference between the university he leaves and the university to which he is going. The Johns Hopkins University has long stood for the most modern method in medicine and the most progressive ideas, whereas Oxford, with a past of glorious traditions in many fields of knowledge, has often lagged behind in the march of medical science. Dr. William Collier, in the President's address at the recent meeting of the British Medical Association, drew attention to the revival in the teaching of medicine which has lately come to the University of Oxford. Twenty-five years ago the medical faculty had fallen from its previous high estate, and the university was no longer a definite factor in the training of physicians. In 1878 bitter complaint was made of the neglect of the study of medicine at Oxford, and there was no unanimity of opinion as to the possibility or desirability of reviving the interest which had lagged. The British Medical Association took up the matter, and following the attention excited thereby petitions looking to the establishment of a medical school, in the modern sense, were drafted and signed by many prominent persons. These efforts bore fruit, and in 1882 Prof. Burdon Sanderson was appointed to the newly founded chair of human physiology and histology, a first step toward the establishment of modern medical education in Oxford. In 1895 Sir Henry Acland retired from the Regius professorship and was succeeded by Sir John Burdon Sanderson, whose resignation now leads to the appointment of Dr. Osler. The gradual development of pathology, the controversy regarding vivisection and the various difficulties both financial and otherwise which the University Medical School has suffered do not here concern us. All these difficulties, it is hoped, are of the past, and Dr. Osler will assume his position under conditions which, though vastly different from those prevailing in this country, will nevertheless allow him the fullest opportunity to develop still further his extraor-

dinary powers as a teacher and leader of younger men. Twenty-two years ago the *British Medical Journal* commented on the appointment of Sir John Burdon Sanderson to the chair of physiology as follows:

" Dr. Sanderson has a grand opportunity. He has sacrificed much in order to take up the noble work of organizing a real school of medicine at Oxford. Success in such a work would be the worthy achievement of a lifetime. There will be a universal feeling of confidence that the man who has now put his hand to the plough will not turn back, but will finally surmount every difficulty to his own high honor and to the great gain of the profession of medicine."

This certainly does not apply with equal force to Dr. Osler. The lapse of time has made many definite changes which will not permit a return to the old regime. At the same time we may easily conceive that the opportunities for leadership will still not be lacking at the ancient university; that Dr. Osler will be equal to the task imposed upon him we have not the slightest question.

THE SLAUGHTER OF ANIMALS FOR FOOD.

THE British Committee appointed in January, 1904, " to ascertain the most humane and practicable methods of slaughtering animals for human food, and to investigate and report upon the existing slaughter-house system," has made its report to Parliament.[1] The word "animal" as used in this report includes only cattle, calves, sheep, lambs and pigs.

The committee consisted of Mr. Arthur Lee, chairman, Shirley F. Murphy, chief medical officer of health of London, and five others. The principal persons examined were the chief veterinary inspectors, master butchers, one member of the Prussian Government, Jewish rabbis and other experts in the slaughtering of cattle. In addition to the published minutes of evidence, an appendix contains full information as to the methods of slaughter practised in foreign countries, especially the well regulated systems in use in Denmark, Germany and Switzerland.

The committee states that it has clearly recognized from the first that it would be futile to recommend any methods of slaughter, however humane, which would be impracticable on the score of complication, time or expense, or which would in any way depreciate the utility or market value of the carcasses for human food. " To do otherwise would not only stultify their recommendations, but would do away with any justification for killing the animals at all. The Committee, therefore, makes no recommendations which, in its opinion, are not strictly business-like and which have not been clearly demonstrated to be practical." The report contains general recommendations, designs for slaughter-houses, detailed methods of slaughter, comments upon the Jewish method, and certain suggestions for proposed regulations.

The conclusions of the committee with reference to the Jewish methods are as follows:

a. The Jewish system fails in the primary requirements of rapidity, freedom from unnecessary pain, and instantaneous loss of sensibility, and it compares very unfavorably with the methods of stunning recommended by the Committee.

b. The preliminary operations of " casting "[2] and of forcing the animal's head into position for the cut, are difficult, painful and objectionable from a humanitarian standpoint.

c. The subsequent operation of cutting the throat is at best an uncertain method of producing immediate loss of sensibility, and frequently causes great and unduly prolonged suffering to the animal.

d. Until some method is devised and adopted for rendering the animal unconscious, previous to the "casting" and throat-cutting operations, the Jewish system of slaughtering cattle should not be permitted in any establishment under Government control.

The committee also suggest the following proposed regulations:

(1) All animals, without exception, must be stunned, or otherwise rendered unconscious, before blood is drawn.

(2) Animals awaiting slaughter must be so placed that they cannot see into the slaughter-house, and the doors of the latter must be kept closed while slaughtering is going on.

(3) The drainage of the slaughter-house must be so arranged that no blood or other refuse can flow out within sight or smell of animals awaiting slaughter, and no such refuse shall be deposited in proximity to the waiting pens.

(4) If more animals than one are being slaughtered in one slaughter-house at the same time, they must not be within view of each other.

(5) None but licensed men shall be employed in or about slaughter-houses.

[1] Report of the Committee appointed by the Admiralty to consider the humane slaughtering of animals, with appendix, presented to both houses of Parliament by command of His Majesty. London, July, 1904.

[2] As a result of the inquiries of the Committee, twenty-one rubber pavements were at once ordered for the slaughter-houses at Deptford, in order to break the fall of the cattle, when "cast" by the Jewish method.

MASSACHUSETTS GENERAL HOSPITAL TRAINING SCHOOL FOR NURSES.

In our issue of June 30 we commented editorially upon a proposed change in the training of nurses at the Boston Children's Hospital whereby they were to receive a part of their instruction at the recently organized Simmons College. We are glad to note the fact that a somewhat similar arrangement has been planned for the nurses of the Massachusetts General Hospital. Hereafter, four months of the three years' course will be devoted to work at Simmons College on the subjects of chemistry, anatomy, physiology, bacteriology and sanitation and household arts. It is naturally neither expected nor desired that in the short time devoted to the study of these fundamental subjects more than an outline can be given. For example, in chemistry it is intended that certain of the common inorganic and organic compounds be described with particular reference to their practical application in the problems of nursing. In bacteriology a somewhat complete general knowledge of the distribution and morphology of bacteria is designed, with such practical matters relating to their modes of development, dissemination, cultivation and microscopic examination as may seem fitting for the nurse. Courses in anatomy and physiology are intended to provide knowledge of the general structure and function of the body as a whole and of its various parts.

The plan provides for knowledge which has heretofore been in great measure given during the actual course of training in the hospital. It is evident that such a plan conduces to the best economy of time and effort. The distractions of a hospital to the novice and the constant presence of the practical sides of her calling must stand in the way of a devotion to the fundamental branches, which should be mastered before the actual work of nursing begins. The equipment and methods of Simmons College will no doubt conduce not only to a readier means of acquiring this knowledge, but also to greater thoroughness. Another step in advance in this training school is the withdrawal of the money allowance heretofore granted student nurses. Hereafter, the students in the school will be required to pay in advance a tuition fee, although certain allowances by means of scholarships are made for those who actually require financial aid. Beyond the regular work in the wards of the hospital the work will hereafter include three months' training in obstetrics in maternity hospitals, three months in the details of private nursing at the Corey Hill Hospital at Brookline, and not less than one month as assistants in the operating rooms of the Massachusetts General Hospital.

THE ST. LOUIS CONVENTION AND OVERSTRAIN.

The National Democratic Convention at St. Louis furnished a sad example of the disregard of the elementary rules of health, and should serve as a warning to the managers of future conventions. If it be alleged that the proceedings of the Republican convention were cut and dried beforehand, the Democrats went to the other extreme, and through lack of preliminary preparation and organization, subjected the delegates and a host of spectators to a physical and mental strain from which many will never recover.

Who knows how many hearts and kidneys which, though not perfectly sound, had been doing their work reasonably well, are now showing signs of failure as a result? Seventy-two hours of work by day and shouting by night, without sleep, must put a severe tax on even robust constitutions. If this sort of thing is made to be a part of the machinery of party organization, it is not surprising that there are citizens who hesitate about actively entering upon political duties.

Members of the medical profession know that men past middle life, and these are for the most part the counsellors and props of a political party, men whose organs have lost some of their pristine superabundance of vitality, cannot draw so heavily on their reserve as in their more youthful days without paying the cost in poor health, a shorter life, or both. Hard work seldom kills; prolonged worry and excitement, coupled with insufficient food and lack of sleep, to say nothing of impure air, may tax human endurance to the breaking point.

Although the science and art of medicine has no political leanings, cares for the rich or poor, high or low, good or bad, Democrat or Republican alike, it seems to us that the Democratic party managers are to be taken to task for so managing, or rather mismanaging, their convention as to imperil the health of a large number of men.

MEDICAL NOTES.

Laboratory for Illinois State Board of Health. — The State Board of Health of Illinois is about to establish a laboratory with the best equipment for bacteriological and chemical

work. The laboratory is particularly needed because of the widespread campaign recently instituted against tuberculosis throughout the state. Heretofore laboratory investigations have in great part been carried on in Chicago, and the complete removal of this work to Springfield, where the laboratory will be located, will allow prompter reports and more economical management. The laboratory is to be open to the physicians of Springfield and its neighborhood.

SMALLPOX IN AND ABOUT CHICAGO.— According to the Bulletin of the Chicago Health Department, eight cases of smallpox were discovered and sent to the isolation hospital during the week ending Aug. 13. One of the patients had a history of doubtful vaccination, and the others had never been vaccinated. It is furthermore announced that in Zion City, presided over by Dowie, there have been 29 cases since June 1. An inspection by the health authorities recently showed sixteen cases in the isolation hospital, removed from the city. The cases were of a mild type and well cared for. Precautions are being taken, disinfection and isolation are carried out with intelligence, but vaccination is refused.

THE RIGHT TO SELL SMUGGLED DRUGS. — It is announced that litigation which has lasted since 1898, involving the right of the United States Government to sell copyrighted and patented goods smuggled into the country has been decided against the government. The dispute arose regarding a large amount of smuggled phenacetin, purchased by local agents from the government, who, when about to sell it, were prevented by an injunction procured by the German manufacturers, the latter claiming the sole right to the name since they had procured a copyright on the word. The manufacturers have finally been upheld, and the purchasers are obliged to return the drug in their possession, and may only recover their loss through a special act of Congress.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon Aug. 24, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 32, scarlatina 12, typhoid fever 34, measles 7, smallpox 0.

MORTALITY IN WORCESTER, MASS., FOR JULY. — The Board of Health of Worcester reports that the number of deaths for July, 1904, was 148, as against 199 for the corresponding month last year, being a decrease of 51, which the Board rightly regards as an excellent showing. In June, 1904, on the other hand, the deaths numbered three more than for June, 1903.

BEQUESTS. — By the will of the late Thomas D. Walsh, bequests of $1,000 each are made to St. Mary's Infant Asylum and five other institutions of semi-medical character in Boston and vicinity.

GIFT OF FIVE HUNDRED DOLLARS TO THE BOSTON FLOATING HOSPITAL. — The managers of the Boston Floating Hospital announce the receipt of five hundred dollars from anonymous persons to be applied to the fund for the construction of a new hospital boat.

OUTBREAK OF TYPHOID FEVER TRACED TO ITS SOURCE. — It is reported that a number of cases of typhoid fever, which have recently appeared in different parts of Boston, have been traced to contaminated spring water in connection with the construction of a sewer in an outlying part of the city. Direct infection appears to have been caused by the carelessness of one of the workmen on this sewer who had recently had a mild attack of typhoid fever. Immediate steps were taken to prevent the drinking of this water, and there is no probability that further cases will develop from this source.

NEW YORK.

APPOINTMENTS FOR STUDY OF PULMONARY DISEASE. — According to the *Journal of the American Medical Association* Dr. Darlington, health commissioner of New York, has selected a portion of the committee for the study of diseases of the lungs, for which recently $10,000 was appropriated. Among those appointed are Drs. Edward G. Janeway and T. Mitchell Prudden of New York, Drs. W. H. Welch and William Osler of Baltimore and Dr. Theobald Smith of Boston.

Miscellany.

THE WOUNDED IN THE NAVAL WAR BETWEEN JAPAN AND RUSSIA.

THE *British Medical Journal* in its issue of Aug. 13 published interesting notes from S. Suzuki, Deputy Inspector General of the Japanese Imperial Navy and Surgeon-in-Chief of the combined fleets, stationed on the "Mikasa," Admiral Togo's flagship, concerning the treatment of wounds on shipboard, of which the following are the conclusions:

(1) First aid dressings are very important if they are applied at all on the spots where men are injured, but nearly half or a little less of all the wounded are carried or come to the surgery without any dressing. The ambulance parties should be stationed at various parts of the ship. The practical and careful education

of ambulance parties is essential to future progress in the treatment of wounds.

(2) The first-aid packages used in navies of different countries are, it seems to me, folded too small, as the wounds inflicted by shell fragments are always larger than those made by small-calibre rifle bullets. These packages are intended chiefly for the army, where small size is essential for carrying purposes, but on board ship size does not matter much. In my experience 4-in. square sterile absorbent cotton wool with ¼-in. or a little more thickness covered with gauze and stitched in a few places around, is a convenient size. To this pad the middle part of a gauze bandage of 8 ft. in length and 4 in. wide should be stitched and kept aseptic as usual. With this we may dispense with the well-established triangular bandage.

(3) The modes of carrying the wounded must be various, as the size of ships varies as well as that of ladders and passages. As a rule, hand carrying is practised in small ships; in the battleships and first-class cruisers stretchers may be freely used if the surgeons impress on the bearers how to handle them quickly. We found a special stretcher made of bamboo and canvas, devised by Mr. Totsuka, of Sasebo Naval Hospital, very useful. No one form of stretchers, however ingeniously made, is suitable for all purposes on board ship.

(4) Choice of place for the surgeries. I believe it is generally accepted that a surgery on board war ships in action should be provided in more than one place. Even in cases where there is only one surgeon on board it is better to have two surgeries in different parts of the ship. It is desirable to choose a place below water line, but every ship does not allow surgeons to do this. I believe in the near future an ample provision for special surgery during action will be made by joint consultation of naval constructors and surgeons.

(5) Slight protection may save serious injury to the body. There are many examples to show that a pocket notebook, knife, etc., have saved men's lives from shell fragments. We have had a few examples in the present war. I dare say that in time every combatant on board war ships in action will wear some kind of protecting mask and jackets; a rifle-proof jacket was devised by the Germans some time ago. It is important to remember that in regard to the disposal of wounded men the non-firing side of a ship is more dangerous than the firing side, that is, the one exposed to the enemy, as the fragments of bursting shells are dispersed in a radiating manner.

(6) Strict observance of aseptic surgery is essential in military as in civil surgery, but the performance of serious operations on board war ships is incompatible with the good progress of cases; it is far better to transfer such cases as soon as possible to hospital ships. The surgeon-in-chief of fleets must take care to secure the fullest efficiency in the use of hospital ships, as non-combatant steamers are desired to be left as far as possible behind the actual seat of war.

SANATORIA FOR CONSUMPTIVES IN GERMANY.

The German Imperial Board of Health [1] gives the following statement: "At the beginning of 1904 there existed in the German Empire more than ninety 'Lung-Sanatoria' with, altogether, 8,000 beds. Of these 2,500 are exclusively for female patients. If we calculate on the average four patients for every bed, in one year, it follows that about 32,000 patients can enjoy the benefits of these sanatoria at the present time. The expense of building and furnishing the sanatoria amounted, up to the present time, according to a moderate estimate, to more than forty million marks (nearly ten million dollars). Beside the existing sanatoria the building of new ones is planned, some of which are in condition to be opened this year. As a basis for building expenses five thousand marks for every bed were calculated. Models and plans for sixty of these sanatoria were exhibited at St. Louis in the German exhibit."

Correspondence.

AMERICAN MEDICAL SOCIETY FOR THE STUDY OF ALCOHOL AND OTHER NARCOTICS.

Hartford, Mass., Aug. 20, 1904.

Mr. Editor: The American Society for the Study of Alcohol and other Narcotics was organized June 8, 1904, by the union of the American Association for the Study of Inebriety and the Medical Temperance Association. Both of these societies are composed of physicians interested in the study and treatment of inebriety and the physiological nature and action of alcohol and narcotics in health and disease. The first society was organized in 1870 and has published five volumes of transactions and twenty-seven yearly volumes of the *Quarterly Journal of Inebriety*, the organ of its association. The second society began in 1891 and has issued three volumes of transactions, and for seven years published a quarterly bulletin containing the papers read at its meetings. The special object of the union of the two societies is to create greater interest among physicians to study one of the greatest evils of modern times. Its plan of work is to encourage and promote more exact scientific studies of the nature and effects of alcohol in health and disease, particularly of its etiological, physiological and therapeutic relations. Second, to secure more accurate investigations of the diseases associated with or following the use of alcohol and narcotics. Third, to correct the present empirical treatment of these diseases by secret drugs and so-called specifics, and to secure legislation, prohibiting the sale of nostrums claiming to be absolute cures containing dangerous poisons. Fourth, to encourage special legislation for the care, control and medical treatment of spirit and drug takers. The alcoholic problem and the diseases which center and spring from it are becoming more prominent, and its medical and hygienic importance have assumed such proportions that physicians everywhere are called on for advice and counsel. Public sentiment is turning to medical men for authoritative facts and conclusions to enable them to realize the causes, means of prevention and cure for this evil. This new society hopes to meet this want by enlisting medical men as members and stimulating new studies and researches from a broader and more scientific point of view. As a medical and hygienic topic the alcoholic problem has an intense personal interest, not only to every physician, but to the public generally in every town and city in the country. This interest demands concentrated efforts through the medium of a society to clear away the present confusion, educate public sentiment, and make medical men the final authority in the consideration of the remedial measures for cure and prevention. For this purpose a most urgent appeal is made to all physicians to assist in making this society the medium and authority for the scientific study of the subject. The secretary, Dr. T. D. Crothers of Hartford, Conn., will be pleased to give any further information.

Truly yours,

T. D. Crothers, M.D.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, AUGUST 13, 1904.

CITIES.	Population Estimated, 1904.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

Deaths reported, 3,516; under five years of age, 1,397; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,447; acute lung diseases 172, consumption 349, scarlet fever 8, whooping cough 17, cerebrospinal meningitis 29, smallpox 2, erysipelas 6, puerperal fever 9, measles 13, typhoid fever 63, diarrheal diseases 814, diphtheria and croup 37.

From whooping cough, New York 4, Chicago 4, Philadelphia 3, Pittsburg 3, Boston 1, Holyoke 1, Northampton 1. From measles, New York 8, Chicago 1, Philadelphia 1, Pittsburg 2, Lowell 1. From scarlet fever, New York 2, Chicago 3, Baltimore 3. From cerebrospinal meningitis, New York 24, Worcester 2, Cambridge 1, Chelsea 1, Adams 1. From erysipelas, New York 4, Philadelphia 1, Pittsburg 1. From smallpox, New York 1, North Adams 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending July 30, the death-rate was 16.4. Deaths reported 4,793; acute diseases of the respiratory organs (London) 48, whooping cough 57, diphtheria 35, measles 156, smallpox 5, scarlet fever 33.

The death-rate ranged from 2.6 in Smethwick, to 29.8 in Liverpool; London 16.0, West Ham 22.1, Brighton 14.9, Southampton 12.1, Plymouth 15.6, Bristol 11.7, Leicester 10.9, Nottingham 20.1, Bolton 13.4, Manchester 20.9, Salford 18.7, Bradford 18.3, Leeds 18.5, Hull 16.4, Sheffield 13.4, Cardiff 11.8, Rhondda 24.7, Wigan 21.6, Merthyr Tydfil 13.6, West Bromwich 14.7.

METEOROLOGICAL RECORD.

For the week ending August 13, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING AUGUST 20, 1904.

A. FARENHOLT, surgeon. Detached from the "Concord" and ordered to the "Monterey."

C. H. T. LOWNDES. Detached from the "Chesapeake" and ordered to the Naval Academy.

V. C. B. MEANS, surgeon. Detached from the "Montery" and ordered to the "San Francisco."

R. G. HEINER, assistant surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the "Southery."

H. B. FITTS, surgeon. Detached from the "Pensacola," and granted leave for thirty days.

RECENT DEATHS.

ROBERT MILBANK, M.D., a well-known New York physician, died on August 4, at the age of fifty-six. Dr. Milbank had gone to Port Chester, on Long Island Sound, to visit a patient, his cousin, who was ill with typhoid fever, and while there, was attacked with cerebral apoplexy, which caused his death in a few hours. He was graduated from the medical department of the University of the City of New York in 1878, and afterwards served as interne in Bellevue Hospital.

ROMEO F. CHABERT, M.D., one of the most prominent physicians of Hudson County, N. J., died at his summer residence at Asbury Park, N. J., on August 1. He was born in London in 1828, and came to America when seven years of age. He had practised for forty-eight years in Hoboken, N. J., where he was the founder of St. Mary's Hospital. At the time of his death he was consulting physician to this institution, as well as to the Bayonne Hospital at Bergen Point, N. J. For many years he was also a member of the Board of Managers of the New Jersey State Hospital for the Insane at Morris Plains.

BOOKS AND PAMPHLETS RECEIVED.

Appleton's Medical Dictionary. An illustrated Dictionary of Medicine and Allied Subjects in which are given the Derivation, Accentuation, and Definition of Terms used throughout the Entire Field of Medical Science. Edited by Frank P. Foster, M.D. Illustrated. New York and London: D. Appleton & Co. 1904.

The Principles and Practice of Gynecology. For Students and Practitioners. By E. C. Dudley, A.M., M.D. Fourth Edition, Revised. Illustrated. Philadelphia and New York: Lee Brothers & Co. 1904.

Diseases of the Stomach and Their Surgical Treatment. By A. W. Mayo Robson, F.R.C.S., and B. G. A. Moynihan, M.S. Lond., F.R.C.S. Second Edition. Illustrated. New York: William Wood & Co. 1904.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otology, Rhinology, Laryngology, Hygiene, and Other Topics of Interest to Students and Practitioners. By leading members of the Medical Profession throughout the World. Edited by A. O. J. Kelly, A.M., M.D. Vol. II. Fourteenth Series, 1904. Illustrated. Philadelphia: J. B. Lippincott Company. 1904.

Original Articles.

CLINICAL TOPOGRAPHY OF LYMPH NODES.

BY F. J. COTTON, M.D., BOSTON,
Assistant Surgeon, Boston City Hospital.

It is a matter of common recognition that most of the surgical affections of lymph glands are of infective origin and secondary to some local focus of infection. It is the writer's impression that we still pay too little attention to these sources of infection, and that we neglect such aid in locating the primary foci as may be obtained by applying our knowledge of the topography of lymph channels.

If we know and remember what region is drained by a given gland or gland chain we shall not only identify and properly treat local foci that might otherwise be overlooked, but may also obtain from the site and character of these foci much help in understanding the glandular conditions. In the case of neck glands in children, for instance, if we, aided by our anatomy, find one case to have an acute infection of the tonsil as the obvious primary cause, while another shows scalp irritation from pediculi, we shall be far less likely to class both cases as what used to be "scrofulous glands." Very often it is only by the aid of our anatomy that we can so identify the source of infection, only by considering this source in connection with the gland condition that we can properly weigh the diagnostic probabilities.

What we need may be called the practical anatomy of the lymphatics. Many of the details of lymphatic connections are so variable that they have hardly more than an academic interest; surgically, no one knows or cares much about them. On the other hand there is a correspondence of given drainage areas with certain larger lymph trunks, and of the latter with certain glands and gland chains, that is sufficiently constant to warrant our consideration.

This paper purports to present an outline of these anatomical facts, as described in the text-books,[1] checked and illustrated by brief notes of cases that have recently come under the writer's notice. Most of these case-notes are from cases seen within the past two months in the men's out-patient surgical department of the Boston City Hospital.

The gland groups will be considered regionally.

Head. Preauricular gland: A small gland, usually single, constant, the most superficial of the parotid group. It usually lies over the jaw-joint a finger's breadth in front of the ear, and receives afferents from the eyelids and orbit, from the root of the nose and from the forehead and the front part of the scalp. It is connected with the other lymph-nodes of the parotid region. It drains into the upper anterior portion of the deep cervical chain.

Case I. Furuncle over left eye. Left (and to less degree the right) preauricular lymph nodes enlarged. No other glands.

[1] Particularly well in Poirier and Charpy's Anatomy.

Case II. Burn of scalp (old and septic) on vertex to front and left. Left preauricular gland enlarged. No other glands except one or two behind angle of jaw — evidently at the top of the deep cervical chain.

Case III. Primary chancre of left lower eyelid. Several weeks' duration. Preauricular gland greatly enlarged; other parotid glands, and some anterior deep cervical glands somewhat swollen.

Case IV. Primary chancre of left upper eyelid. Has been under treatment. Left preauricular gland still large — also a couple of glands of the parotid group.

Case V. Tubercular suppurating neck glands — whole lymph system of left neck involved. Said to have been primary in submaxillary region. Preauricular gland now distinct though fluctuant — evidently involved by infection "against the current."

Case VI. Septic wound above outer edge of orbit. A small hard gland *above* the zygoma in front of the ear. No other glands. This case is of interest from the unusual position of the gland above, not below, the zygoma.

Parotid group of glands: Lymph glands are scattered on and in the parotid under the aponeurosis in some number. They share to some extent in the drainage area of the preauricular gland and also receive some afferents from part of the parietal scalp, from the external and middle ear, and perhaps from the back of the nasal fossæ. They drain into the upper end of the deep cervical chain.

Case VII. Boy of twelve. Shows an adherent node over the lower part of the right parotid. General glandular enlargement throughout the neck, especially the posterior glands and those of the supraclavicular chain. On the surface of the right sterno-cleidomastoid are two large glands. On the left are two suboccipital glands, one at the usual site, the other near an inch below it. Has a discharging chronic otitis on the right. Pediculi capitis (also large boggy tonsils).

Mastoid: Anatomically there are two or more glands. Clinically there is at least one situated constantly just behind the mastoid. It is the enlargement of this which, with the occipitals, is supposed to be so important a sign of syphilis. These glands drain the parietal scalp, and in part the ear and external auditory canal. The afferents run through and about the sternocleidomastoid into the upper end of the deep chain *at the back*.

Case VIII. Single gland behind mastoid with scar over it. Man of thirty-four. Old suppurative otitis in infancy.

Case IX. Fluctuant mass below and behind ear in boy of fourteen. Two months' duration. Was an abscess involving a gland in front of mastoid with enlargement of the upper glands of the deep cervical chain. Mild eczema of the scalp; seborrhea. No other cause found.

Case X. Young woman. Pediculi of scalp. Mastoids and suboccipitals on both sides swollen, especially a gland just on right mastoid process and behind it.

Suboccipital glands: One to three in number, on each side — one said to be always present — size small; situated under the aponeurosis just below the superior curved line at the edge of the trapezius on the complexus. Receive affer-

ents from the posterior portion of the scalp.[2] Efferents are divided between the upper posterior portion of the deep chain and the superficial posterior chain.

CASE XI. On the right side are two moderate-sized swollen glands at normal suboccipital site. Just above them an ulcer following the imperfect removal of a papilloma. Girl of eleven.

CASE XII. Ulcer of base of occiput (staphylococcia) in small child. Duration of one year. Suboccipital glands much enlarged.

CASE VII. Two suboccipital glands on left from pediculi (see above).

Facial glands: The facial glands are essentially inconstant. There appear at times

(*a*) Nasal and infraorbital glands.

(*b*) Buccal — on the external surface of the buccinator muscle.

(*c*) Supramaxillary. This group, like group (*b*), are likely to follow the line of the facial vessels. A gland of this group on or near the lower edge of the jaw is not infrequently palpable in normal individuals. All these facial glands drain to the submaxillary set.

CASE XIII. Syphilitic chancre of the upper lip on the left side; recent infection in young male of twenty-five. Enlarged glands at first only of the supramaxillary group along the facial vein: secondarily, the posterior glands of the submaxillary group became involved.

Submaxillary: There are three to six glands under the aponeurosis and platysma and external to the submaxillary salivary gland running from near the chin to the angle of the jaw. They receive drainage from

(*a*) The last mentioned group of glands.

(*b*) The external nose, cheek and upper lip (directly or through *a*).

(*c*) The gums and the fore part of the tongue.

The efferents run to the deep cervical chain — especially to a gland at the bifurcation of the carotids, but also to glands lower down.

CASE XIII. Woman of thirty. Chancre of right cheek; extreme swelling of submaxillary glands on the right.

CASE XIV. Man of thirty, malignant pustule (anthrax) of right cheek, two enlarged glands well back in the submaxillary set; no others.

CASE XV. Child of one. Swollen lymphatic gland, submaxillary, one only. Bad teeth and sore gums.

CASE XVI. Child of six. Alveolar abscess from right lower bicuspid, outer side. Distinct, tender lymph nodes on submaxillary salivary gland.

CASE XVII. Infected root cavity of bicuspid on left in girl of eighteen. Glands of left submaxillary set much enlarged. Removed under ether. Extend from angle of jaw forward. No other groups involved.

Submental and suprahyoid: These two groups are hardly separable. Between the digastries near the median line are one to four glands. They drain the chin, the outside of the lower lip and part of the mouth. Their efferents run to the submaxillary glands in part, but especially to a gland in the deep cervical chain at the level where the omohyoid crosses the carotid.

CASE XVIII. Man of twenty-five. Stomatitis, especially severe between lower lip and gums. All glands of suprahyoid and submental chain swollen. No others. Subsided under treatment.

CASE XIX. Boy of eleven. Impetigo of lower lip near left corner of mouth. No glands except one small submental, and one anterior suprahyoid on left.

CASE XX. Man of sixty. Advanced cancer of whole lower lip. All suprahyoid gland chain enlarged; also a few of the anterior upper deep cervical chain.

CASE XXI. Cancer of lower lip. One submental gland.

Lingual: On the hyoglossus and genio-glossus muscles are a few small glands to which the trunks of the posterior third of the tongue drain. From here the channels run to the upper glands of the deep cervical chain.

Internal maxillary: In the pterygo-maxillary space at the side of the pharynx lie glands receiving the drainage of part of the nasal fossæ and the roof of the mouth. They empty into the deep cervical chain direct or through the parotid nodes.

Retropharyngeal: One or two glands lie behind the pharynx on the rectus capitis anterior. They drain part of the nasal fossæ and nasopharynx and the Eustachian tube and empty into the glands of the deep cervical chain that lie *behind* the main vessels. These glands are the source of retropharyngeal abscesses.

Subhyoid: There are a few glands over the larynx and trochea, inconstant in distribution, including a group lying on or near the recurrent vessels. These last run down to the mediastinal glands, the others mainly out and down to reach the deep cervical chain low down.

In the neck proper there are three main groups of glands: the superficial, the supraclavicular and the deep group lying near the vessels. There are normally no glands on the nape (but see Case VII). The *superficial glands of the neck* lie in a general way *on* the sternocleidomastoid and more especially about the course of the external jugular vein; there is also a group of two or three along the anterior jugular vein. The superficial glands are especially found toward the upper region of the neck. Such is the book description, but as a matter of clinical fact, obvious superficial glands lie not only on, but perhaps even more often a little *behind* the sternocleidomastoid muscle, and are more often palpable in the middle of the neck than higher up.

These superficial glands drain in part the parotid region and the back part of the scalp. It seems clinically that more of the general posterior scalp area falls direct to their share than is drained through occipitals and mastoids. The efferent trunks run in part to the deep chain, in part to the supraclavicular glands.

The *supraclavicular* chain is likewise superficial and not definitely marked off from the last group. They lie in the supraclavicular triangle,

[2] Some part of the lateral and posterior surface of the scalp drains into trunks which run neither to mastoid nor occipital, but direct to the neck glands, both of the superficial and deep groups.

usually in a vertical chain, receiving drainage not only from the other superficial glands and trunks in the neck, but also efferents from the axillary glands. Their efferents in turn join with those of the deep chain to empty into the subclavian vein.

Superficial cervical:

Case XXII. Boy of six. Mass of acutely enlarged glands on the sternocleidomastoid close to the clavicle. On left, other superficial neck glands also enlarged. Many pediculi capitis.

Case XXIII. Man of twenty-four. Mass of glands on and behind the sternomastoid at middle of neck. Two or three glands above this and the whole supraclavicular chain moderately enlarged. Has many pediculi.

Case XXIV. Girl of ten. Irregular chain of glands superficial at back edge of sternomastoid on left. Few on right similarly placed. Many pediculi.

Case VII. General enlargement of neck glands. Two glands *on* sternomastoid (see above).

Case XXV. Colored male of twenty-five. Ulcerating tubercular glands of right side of neck. All chains involved but two gland masses are distinct *on* the sternomastoid just below the middle of the neck.

Case XXVI. Girl of eleven. Gland swellings (and cellulitis) all posterior to sternocleidomastoid in mid neck. Pediculi many. Subsided after killing pediculi after a little more than two weeks.

Case XXVII. Girl of nine. Glands all posterior to sternocleidomastoid; superficial abscess. Pediculi.

Case XXVIII. Boy of five. Suppurating gland at back edge of sternocleidomastoid, one month duration. Pediculi.

Case XXIX. Girl of fourteen. Glands under back part of sternocleidomastoid and in supraclavicular region — several months' duration. Pediculi many.

Case XXX. Boy of seventeen. Glands, unilateral, at back edge of sternocleidomastoid, suppurating for two weeks. Pediculi many.

Case XXXI. Girl of twenty. Like case, three months' duration. Glands of anterior deep chain also involved. Pediculi many.

Case XXXII. Girl of six. Glands at back edge sternocleidomastoid. Many pediculi. Cured by cleaning and poultice.

Deep chain of neck: These comprise the largest main chain of the neck and the most glands. They lie under the sternomastoid in a rather irregular plexus of freely anastomosing nodes extending from mastoid process to subclavian vein and backward to the supraclavicular triangle. There are from fifteen to thirty in all, mostly in the upper half of the neck and usually few or none below the omohyoid. They may be divided roughly into external and internal: The external group anastomoses with the supraclavicular and receives drainage mainly from the back of the neck and head. They are relatively small glands. The internal group lies on and about the internal jugular vein; it is composed of larger glands. There is one of especial size (palpable in any thin neck) at the level of the hyoid cornua, another rather large one just above the point where the omohyoid crosses the vessels. More or less glands — hardly a chain — lie internal to and beneath the vessels. As to the details of drainage — the trunks from the occiput and nape and the efferents from the posterior glands reach the external chain; those of tongue and nose and throat empty into glands of the internal set mainly at the level of the large gland opposite the hyoid or at a higher level. This chain also receives the drainage of the face and the efferents of the submaxillaries at about the same level.

The efferents join with those of the more superficial glands to empty with the thoracic duct on the left, to a trunk on the right that reaches the subclavian vein direct.

Case XXXIII. Boy of ten. Elastic swelling of the large gland below digastric, right and left. Other glands of deep chain very little enlarged. Tonsilitis two weeks ago.

Case XXXIV. Girl of eleven. Glands below digastric right and left greatly swollen; few other glands. Has subacute catarrhal tonsilitis.

Case XXXV. Girl of twenty. Carotid glands, right and left, swollen several weeks and growing. No other glands. Follicular pharyngitis. No other source.

Deep chain, general anterior enlargement:

Case XXXVI. Boy of seventeen. Acute, swollen glands on left, only. Deep cervical chain only. Whole mass involved, anterior perhaps more. Large, boggy tonsils — pharyngitis.

Case XXXVII. Child of one year. Deep cervical glands all large, especially anteriorly — one side only subacute. Obvious infection of gums around bad teeth on this side.

Several cases of advanced or operated generalized tubercular glands are not here noted.

Lower glands of deep chain:

Case XXXVIII. Man of fifty. Tonsilitis, follicular. On right side whole deep chain swelled, this subsided and there then developed a deep gland mass in the lower anterior chain within an inch and a half of the clavicle. Deep abscess; operation.

Lymphatics of the arm: There are typically no nodes below the elbow, but not infrequently there are said to be atypical glands, as in the following case:

Case XXXIX. Man of forty. Sepsis from slight wound on dorsum of second finger. There was a red line of lymphangeitis, running from the wrist through the bend of the elbow to the axilla. On this line four inches above the wrist on the dorsal side, externally, was a lymph-node the size of a pea; subcutaneous, movable, tender. The epitrochlear gland was not involved. In the axilla were three or four small tender glands of the pectoral or median chain, only.

Epitrochlear gland: This is the lowest lymph node in the arm usually. It lies superficially 3 to 4 cm. above the internal epicondyle on the fascia. There may be two, rarely three, glands in place of one. The general position of this gland is familiar from the examination for suspected syphilis; it is often missed, however, not always by students alone, on account of variation in position. Not infrequently it is much higher than we expect, rarely lower, almost always on or just in front of the edge of the intermuscular septum which is palpable in this region.

The tributary region the trunks of which pass to the epitrochlear includes the ulnar surface

of the forearm in its lower half and two or three fingers, with the ulnar border of the hand. This area is not constant, of course, in detail, and some of the cases which follow show both more and less than the usual areas transmitting infection to this gland.

CASE XL. Furuncles of the hand scattered on ulnar and radial side. Epitrochlear gland moderately enlarged. Lymphangeitis in a red line up from furuncle on radial side of wrist toward the axilla. Axillary glands much enlarged.

CASE XLI. Man of thirty. Superficial wound of little finger — slight sepsis. Secondary furuncle on ulnar side of wrist. Epitrochlear gland much swollen. One gland in axilla in middle (not humeral) chain.

CASE XLII. Man of twenty-five. Septic man-bite of knuckle of third finger. Epitrochlear enlarged. Soreness also in axilla, nothing palpable.

CASE XLIII. Man of twenty-five. Superficial skin sepsis of little finger. Line of red lymphangeitis to the greatly enlarged epitrochlear gland. Nothing in the axilla.

CASE XLIV. Man of twenty-four. Septic wound of the ulnar side of the wrist with cellulitis and ascending lymphangeitis. Slight enlargement of epitrochlear. Axillary glands swollen.

CASE XLV. Girl of eight. Wound of ulnar side of forearm half way up. Greatly enlarged and tender epitrochlear gland. Axilla negative.

CASE XLVI. Superficial sepsis of the dorsum of hand on *radial* side — red lymphangeitis around back of ulnar side, thence to a swollen epitrochlear gland. No axillary gland enlargement.

CASE XLVII. Male adult. Superficial sepsis of *index* finger. Vague red lines up the forearm. Epitrochlear gland greatly swollen and tender. Axilla negative.

Deep glands exist along the brachial vessels — few and inconstant. The delto-pectoral glands are present in 14% of cases (Grossman, quoted by Poirier). There are but one or two small glands lying at the shoulder in the groove between deltoid and pectoral. The writer has never seen any of these recognizably enlarged.

Axillary glands: The glands of the axilla lie under the aponeurosis, mainly well up in the axilla. They are usually classified in five groups.

The *humeral*, four or five in number, lying along the vessels on the inner side of and often on the vein. These are supposed to drain nearly all the arm.

The *thoracic* divided into an *upper* group, two or three at the second and third intercostal spaces under the pectoralis major, draining chest and breast, and a *lower* group at the fourth and fifth space lying along the external mammary artery. These drain the wall of the thorax and upper abdomen.

The *subscapular* group are a few nodes which lie about the dorsalis scapulæ and receive drainage largely from the lower part of the nape and the scapular region and the upper back. There is a set sometimes described as the intermediate chain, not a chain properly, but a set of glands interrupting the general anastomosis of the other groups.

The *subclavian* glands are a short chain of six to twelve glands between the axillary vein and the serratus magnus muscle and above the upper edge of the pectoralis minor. They receive little or no primary drainage but receive the efferents of nearly all the other glands of the axillary group. They anastomose also with the glands of the neck. Their efferent vessels empty into the subclavian near the external jugular.

See also Cases XXXIX, XL, XLI.

CASE XLVIII. Male of twenty. Sepsis of second finger, lymphangeitis red up through bend of elbow along inner biceps edge to inner axilla. Glands of pectoral group *only* are palpable.

CASE XLIX. Male of thirty-five. Burn of radial side of dorsum of hand. No epitrochlear. Axillary glands enlarged; median and humeral groups.

CASE L. Burn three inches above the wrist on ulnar surface. Epitrochlear not enlarged but glands in axilla swollen.

CASE LI. Incised wound of second finger on palmar side, lymphangeitis up the arm through bend of elbow along inner side of biceps. Glands in axilla on thoracic side *only* — two high up.

CASE LII. Late cancer of breast. Massive metastases in lower pectoral chain, but upper glands also found infected at operation.

CASE LIII. Drained septic empyema wound in mid-axillary line — ninth rib excision — glands in axilla of pectoral (lower) and intermediate chains.

Glands of leg: The lowest glands in the leg are the inconstant *anterior tibial* group, lying deep in on the upper part of the course of the anterior tibial vessels. The *popliteal* glands are the lowest constant ones. Even these are only exceptionally to be found enlarged. They are subaponeurotic, small and rather deep, and the relative frequency of bursal enlargements in this region renders a differential diagnosis not always easy.

There is usually a gland lying relatively near the surface, near the external saphenous vein, receiving drainage from the outer side of foot and ankle. The next deeper set receives the efferents from the anterior tibial ganglion and those accompanying the vessels, and the deepest glands drain the joint and its surroundings. The writer has not seen these deeper glands enlarged, the superficial one only twice. As a rule, superficial leg infections seem to give rise to inguinal enlargements, the lower glands being skipped.

Inguinal glands: The glands ordinarily referred to as inguinal are the superficial sets, including the horizontal chain along Poupart's ligament and the shorter vertical set in Scarpa's triangle. They lie in the deep layer of the superficial fascia along most of the length of Poupart's ligament, and down in front of the femoral vessels for about three inches. Beyond the division into horizontal and vertical groups there is no sharp division of groups.

The *vertical* inguinal or femoral chain drain the superficial tissues of the leg in the main. In the *horizontal* group the upper and inner glands drain the scrotum and the surface of the penis (except near the meatus) and receive some of the lymphatics from the perineum and anal region and usually those from the pubes and abdomen below

the umbilicus. The outer glands drain the buttocks and part of the perianal region. The glands of the superficial group drain in the main to the intrapelvic glands (external iliac, etc.) by way of the crural ring. They anastomose also with the deep inguinal glands.

Inguinal and femoral:

Case LIV. Male of forty. Slight sepsis over tibia. Inguinal glands swollen, vertical group *only* — none of horizontal chain.

Case LV. Varicose ulcer over lower tibia. Two large glands of saphenous chain. No swelling of horizontal glands.

Case LVI. Horse kick on front of thigh one week ago — slight local sepsis. Enlarged oblong gland (1) at femoral ring. Slight swelling of three or four of horizontal set.

Case LVII. Male of forty. Enlarged glands, right, especially of saphenous chain but also of horizontal. History of recent strain lifting. Careful examination shows no local primary lesions.

Case LVIII. Enlarged gland (1) of saphenous chain. Two small glands internal to this over pectineus and well below Poupart's ligament. Careful examination shows no primary lesion. History of bubo fifteen years ago.

Case LIX. Enlargement (acute) of scattered inguinal glands all just below Poupart's, belonging to the lower middle part of the horizontal chain. Primary focus a furuncle near anus on left.

Case LX. Furuncle on buttocks a hand's breadth from anus. Red lymphangeitis around buttock to outer upper glands of horizontal chain.

Case LXI. Eczema from pediculosis pubes. Enlarged glands both sides — of horizontal chain mainly at the inner end.

Case LXII. Scabies mainly limited to base of penis and pubes. Suppurating glands on both sides at inner end of horizontal chain. Other glands moderately swollen.

Case LXIII. Small scrotal epithelioma on the left side, of some years' duration. Hard gland masses of lower inner horizontal inguinal chain on left only; they belong to the superficial glands. Question of adhesions and involvement of deep femoral chain.

Case LXIV. Woman of thirty-five. Small septic abrasion on the front of the ankle. Suppurating bubo of the vertical femoral chain in the groin. Horizontal set not involved.

As to bubo infection from the penis and scrotum, the writer has not kept accurate notes of glands involved. Most of them seem dependent on ulcers of prepuce or just behind corona, and the upper inner superficial glands are those involved.

As to glands from urethral involvement, the writer has watched for years a series, certainly including twelve hundred cases of gonorrhea, and has seen gonorrheal bubo (except where there was local external cause, *e. g.*, associated ulcers or balanitis) in not over three or four cases. The ordinarily reputed "bubo from gonorrhea" is a myth, as much against clinical as anatomical evidence.

The *deep inguinal glands* lie under the crural group under the fascia. They are only two or three in number, small, and rarely to be identified clinically. Where a bubo involves the crural group and is adherent to the deep parts, we may be justified in inferring that this group is also affected. One of the glands (Cloquet's gland) lies in the femoral canal and derives clinical importance from this fact as its enlargement is said to cause pain and circulatory disturbances. These deep glands drain the deeper tissues of the leg, receiving also vessels from the glans penis and from part of the superficial inguinal glands, the efferents of which pass mainly by this route to the iliac chain.

The lymphatics within the pelvic and abdominal cavity are of little diagnostic importance; the anatomy may be dismissed with the statement that the lymph channels and glands follow the general course of the veins toward the receptaculum chyli. For clinical purposes it is important to remember that the external iliac group receive the efferents of the superficial inguinal group, as well as some direct drainage, urethra and glans for example. These efferent trunks reach the pelvis in part through the crural, in part through the inguinal ring. This is the only direct drainage; all lymphatics from the leg reach other glands before they reach the pelvis; the scrotum and perineum and all of the superficial surface of the penis except the glans drain to the inguinal glands of the superficial set; the testis drains with the cord through the inguinal canal direct to the lumbar glands of the lateral series, corresponding to the fetal position of the testis.

Case LXV. Malignant disease of scrotum — glands of superficial inguinal chain enlarged.

Case LXVI. Male twenty-four. Carcinoma of left testis. Glandular mass in abdomen to the left in the region of the left kidney. There is no discoverable enlargement of other glands than this lumbar set.

The urethra in common with the meatus drains direct to the glands of the iliac sets. This explains the clinical fact that adenitis from gonorrhea, uncomplicated with balanitis or sores, is a rarity, despite the usual clinical teaching. The writer has never yet seen a case of *suppurating* adenitis from urethral infection. Nor has he found the simple gland enlargement present in more than a trifling per cent of urethritis cases.

It is to be remembered that there is in the inguinal series a free cross-anastomosis from side to side taking place in front of the pubis.

Case LXVII. Man of twenty-five. Small, partly healed chancroid on left side of prepuce. Glands swollen in both groins but predominantly *on the right*.

No effort has been made to include in this paper the anatomy of such glands as are out of reach of surgical palpation, for only these palpable ones have any diagnostic value. The writer feels convinced of the practical value of a knowledge of such gland chains as are within reach of examination. It is not claimed either that the correspondence of glands with drainage areas is exact, or that ascertaining the anatomic source of infection will necessarily determine the character of the process. Of course, it cannot do this, but it can help. The writer is very sure

that a more exact attention to and some familiarity with the grouping of glands and their drainage areas will set us right in regard to:

(*a*) Many so-called " scrofulous " neck-glands in children which show up first in the posterior deep and superficial glands. Sometimes they are tuberculous; in nearly all cases, however, they are septic; in all cases they are traceable to primary scalp irritation, usually from pediculi. Remove the pediculi, make small incisions for the pus, and the great majority will get well promptly without the enucleation now so frequently carried out for these as well as the really tuberculous cases.

(*b*) Buboes of unknown origin, non-venereal, lying low in the groin, due to a septic focus on the foot or leg, which is often overlooked by patient and physician.

(*c*) True inguinal buboes, associated with a gonorrhea, but almost never due to it, but secondary to some septic process under the prepuce which should be but rarely is found.

Of the service of anatomical knowledge of neck and groin glands there is no doubt; elsewhere such knowledge is less obviously useful, but we are unlikely to grow too familiar with it.

This paper contains nothing new in theory or fact, and the cases appended are simply illustrative, but the writer hopes that the practical anatomy under consideration may be refreshed for others in the reading as it has been for him during the observation of this list of cases.

SURGERY ON OLD MEN.

BY WM. H. ARTHUR, M.D.,
Major and Surgeon, U. S. Army, Washington, D. C.

THE hospital of the United States Soldiers' Home offers unusual opportunity for observing the effect of old age, with its accompanying disabilities, in reducing the chances of recovery from serious surgical operations, involving prolonged anesthesia; and, during my service here of about ten months, I have been a good deal impressed with the fact that old men are much better subjects than, I believe, is generally supposed.

The inmates of this Soldiers' Home are divided into three classes:

(1) Honorably discharged soldiers of the regular army of over twenty years' service.

(2) Men discharged on surgeon's certificate of disability, at any age, or after any length of service.

(3) Any man who has served in the regular army, and who has, subsequently to his discharge, become so far disabled as to be unable to earn his living.

Some of the inmates are veterans of the Mexican war; many of them were mature men at the outbreak of the Civil war, and most of the younger men are the débris of the Spanish war and the military operations in the Philippines. This clientele does not seem to offer a very promising field for surgery. Many of these men suffer from chronic alcoholism, general arterio-sclerosis very far advanced, chronic nephritis, cystitis, tabes, diabetes, syphilis or inoperable visceral cancer. Heart diseases (including neuroses, valvular defects and degenerations of the heart muscle) and chronic pulmonary tuberculosis, extensive emphysema and chronic bronchitis are very common. Indeed, it is the exception to find a man over sixty in the hospital entirely free from one or other of these diseases, and still many of them present indications for operation, almost mandatory, if what is left of their lives is not to be intolerable.

Out of 65 operations I have performed here of sufficient severity to require general anesthesia, 22 were done on patients averaging 70.4 years of age (the youngest being sixty-two, the oldest eighty-five) and, as it is these cases only that present anything of interest in this connection, the others will not be considered.

My experience having been for twenty-three years among an entirely different class of cases, soldiers on active duty, healthy, vigorous, picked men, in the prime of life, it was with considerable misgiving that I began operating upon the old, broken-down men who are treated in this hospital. It was very necessary, in the beginning, in order to secure and retain the confidence of these men (who have very little to occupy their minds, talk much among themselves about their ailments, and, I imagine, watch and criticise their doctors very closely), that the first cases should recover promptly, or my surgical usefulness at this hospital would be lost. I was fortunate in finding here an excellent first assistant and a very skillful and experienced anesthetist, with a record of 586 administrations at this hospital, without a death traceable to the anesthetic. There is also a surgical nurse who has had long experience in the preparation of instruments, suture-materials and dressings, and a very well-equipped operating room, clean, fairly well lighted and of good size. The governing board of the Soldiers' Home is wisely liberal in providing anything asked for that can be of any use in caring for the sick. The hospital accommodates 120 patients and will soon be enlarged so as to take in 70 more. The medical side of the hospital is the most important part of the establishment, but does not concern us at present.

The operations in the 22 cases under consideration comprised:

OPERATION		RECOVERED	DIED
Amputations,	4	3	1
Hernia, inguinal,	8	8	0
Hemorrhoids,	3	3	0
Exploratory laparotomy,	2	2	0
Ventral hernia,	1	1	0
Lithotomy (suprapubic),	1	1	0
Trephining and removal of depressed bone of skull,	1	1	0
Varicose veins,	1	1	0
Nephrectomy,	1	1	0

These were performed in the following order:

NO.	NAME	AGE	OPERATION
1	Sherborne,	72	Amputation, middle right forearm.
2	Tetzner,	68	Extensive internal and external hemorrhoids, clamp and cautery.
3	Kinsella,	67	Exploratory laparotomy, general plastic peritonitis, cause unknown.
4	Wilson,	66	Suprapubic cystotomy for stone.
5	White,	65	Left inguinal hernia.

NO.	NAME	AGE	OPERATION
6	Schmidt,	75	Cystic degeneration left kidney, nephrectomy.
7	Schaeffer,	74	Enormous scrotal hernia, left inguinal, partly reducible.
8	Mosher,	69	Amputation, thigh, two inches below trochanters, senile gangrene.
9	Roensch,	64	Amputation, middle finger right hand, Dupuytren's contraction.
10	Hoffman,	84	Hernia, right large scrotal with hydrocele.
11	Hough,	69	Extensive external and internal hemorrhoids.
12	White,	65	Right inguinal hernia.
13	Schantz,	69	Ventral hernia.
14	Nadin,	65	Inguinal hernia, right.
15	Cunningham,	71	Inguinal hernia, left.
16	Weissker,	70	Varicose veins, both legs. (12 resections in all.)
17	Scantling,	78	Trephining and removal of depressed bone of skull.
18	Clark,	62	Left inguinal hernia.
19	Schantz,	69	Exploratory laparotomy for acute intestinal obstruction, appendix removed, obstruction relieved.
20	Clark,	62	Right inguinal hernia and bunion right foot.
21	Blum,	74	Amputation, middle left leg, senile gangrene.
22	Kernan,	85	Extensive internal and external hemorrhoids.

REMARKS, MAY 23, 1904.

No. 1. This man has symptoms of cancer of stomach, inoperable.

No. 2. This patient is a hemiplegic, apparently much older than age given.

No. 3. Some improvement followed operation.

No. 4. A very feeble man with weak heart, apparently much older than age given. Has symptoms of malignant disease of stomach.

No. 6. An unusually vigorous man for his age.

No. 7. Uninterrupted recovery, union *per primam*.

No. 8. Died on fifth day after operation, no circulation in flaps, obliterating endarteritis of all arterial trunks.

No. 10. Union *per primam*, recovery uneventful.

No. 11. Clamp and cautery.

No. 14. This man suffers from chronic pulmonary tuberculosis.

No. 17. Old depressed fracture of thirty years' standing, symptoms (incessant headache and frequent vomiting) relieved.

No. 19. Obstruction caused by appendix adherent at tip, gut slipping under it.

No. 20. Bunion cured by resection of proximal end of first phalanx of great toe.

No. 22. Clamp and cautery.

Many cases of enlarged prostate have come under observation, but there were only two in which operation was indicated, and these occurred in men slowly dying, one from chronic pulmonary tuberculosis, and the other from cancer of the pancreas, and as they could be kept comfortable by frequent catheterization, the prostatectomy was not performed.

The one case among the twenty-two that ended fatally (this man died on the fifth day after operation) was a case of amputation two inches below trochanters for senile gangrene of lower extremity. There was no oozing from the flaps, the femoral arteries were obliterated, no attempt at union resulted and the stump became gangrenous. This man had three years before lost the other lower extremity (amputated at about the same point) for the same cause. He was sixty-nine years of age and in general poor condition. The operation was done at the patient's earnest solicitation, to relieve intolerable suffering in the extremity.

The hernias were all varieties of inguinal, incomplete, complete, direct, indirect, and in two cases (7 and 10) enormous scrotal, only partly reducible. In all these cases plaited silk was used for the deep line of sutures, as in many of them the tissues were not very strong and a permanent suture material was necessary. I see no reason so far to regret using this material, and have since used it here in a number of cases among younger men not reported in this paper.

The anesthetic used in all these cases was chloroform, until the patient had passed the stage of excitement, followed by ether throughout the operation. In cases unusually debilitated a careful watch was kept on the blood pressure with a sphygmomanometer. In one case only (14) was it necessary to hasten the operation on account of threatened collapse of the patient. In this case an attempt had been made by some one, years before, to cure the hernia by injecting the sac with some irritant. This had resulted in producing tough adhesions of the contents to the wall of the sac, and the patient becoming very weak during the attempt to completely free these adhesions, which would have taken a long time, the separation was only partially completed, the sac was only partly removed, stitched up rapidly instead of being ligated, and returned. The patient made a good recovery from the operation, is still living after four months, and has had no symptoms referable to the hernia, which has shown no tendency so far to recur. In another case (12) (bilateral hernia) the patient's condition during the first operation was so poor, that operation on the other side was deferred until later. Both sides have now been closed. Case 7 presented an enormous scrotal hernia (eight inches long, five inches diameter) in a very fat subject, seventy-four years of age. The hernia was partly reducible, and the sac was found to contain about eighteen feet of small intestine, with a mesentery loaded with fat and no omentum. The internal ring had to be enlarged upward before this mass could be reduced. Six months later this patient had some symptoms of obstruction, but they passed away without necessitating laparotomy. The hernia after eight months has not returned, and the patient is now in good general health. Case 6 was of interest. The patient was seventy-five years of age. He presented a large, elastic tumor in the upper left abdominal quadrant. Laparotomy (incision in left semilunar line) disclosed a large cyst containing about 600 cc. of clear fluid. The case was treated like an ovarian cyst (partly emptied through canula and then brought out through incision) and proved to be a cystic degeneration of the left kidney, very little kidney tissue remaining; the entire mass was removed. This man, who was an unusually vigorous man for his age, made an uninterrupted recovery, and is now engaged as "range rider" at Fort Riley, Kan.,

making daily a trip over that large reservation, either on horseback or in a buckboard. He writes that he is entirely well. One case (12) developed a circumscribed apical pneumonia three days after operation, but his recovery from the operation was not materially delayed, the pneumonia remaining circumscribed, and clearing up rapidly after a typical crisis.

The only conclusion to be drawn from these cases is that we need not hesitate to operate even on very old men; that their chances are rather better than is generally supposed, and that in view of the record of the anesthetist at this hospital, who has been administering the anesthetics for fourteen years without a death (586 cases in all), it would appear that general anesthesia is not so dangerous for old people as we are led to believe.

The other forty-three operations being all among men below sixty years of age, are of little interest in this connection, except that their recovery without infection in any case shows that the technic followed here secures very fair results, and I believe that among old subjects with limited resistance, great care to secure asepsis is pre-eminently necessary, for I am sure that, once infected, the tissues of debilitated subjects would offer little resistance, and their destruction would be very rapid and extensive.

In every operation in this hospital, the operator, the first and second assistants and the assistant in charge of the instruments have worn rubber gloves, to which precaution I give the principal credit for the fact that no evidences of infection have been seen in any of the cases operated upon here.

It is not of course safe to draw general conclusions from such a limited number of cases, twenty-two, but the anesthetic record of this hospital (586 cases without a death), when we consider that 30% at least, and more, probably 40%, of these cases were men above sixty years of age, seems to me worth reporting. Spinal anesthesia was used in one case here before my arrival, but the results in that case were so alarming, and general anesthesia has been so apparently free from danger, that it has not been repeated.

Since writing this paper a case has come under observation here that is of interest in this connection.

John Saunders, late Co. F, 19th Infantry, aged eighty-nine, admitted to the Home, April 20, 1904, and immediately sent to hospital suffering from senile gangrene of both feet. This patient was in poor condition, weak and anemic. He suffered from occasional anginoid attacks, not very severe. Heart sounds very distant and feeble, pulse rapid but regular. Radial pulse imperceptible as the result of sclerosed condition of radial arteries. Both feet about equally affected, all toes becoming gangrenous, no posterior tibial pulsation. Popliteal pulse fairly good. This man suffered excruciating pain in the feet and legs. Anodynes had little or no effect, morphia hypodermically administered up to 1.5 grams in 24 hours did not afford relief, the patient seeming to have an idiosyncrasy for this drug, being apparently unaffected by it.

On his earnest solicitation on June 18, both legs were amputated simultaneously, at junction of middle and upper third, the house surgeon removing one and I the other, by circular operation. This man made a good recovery, is still living, August 26, and has complete relief from his suffering, which was very severe before operation. Union was by first intention in both stumps.

MENTAL DEFECTIVES.

BY BERTHA C. DOWNING, M.D., LEXINGTON, MASS.,

Past Supt. of School Department of New Jersey Training School for Feeble-Minded.

IN July, 1848, Dr. H. B. Wilbur, a young physician who had been practising medicine in the village of Barre, Mass., opened a private school for idiots. Without knowledge of the experience of others to guide him, he had to study out his own methods and systems. His success in the work is so well known it needs no mention. This was the first school for idiots that was established in America.

Dr. S. G. Howe, Superintendent of the Perkins Institute for the Blind, opened a similar school for mental defectives, at South Boston, in October of the same year, known as the Massachusetts Institution for idiots. Dr. Howe's largest interest, however, lay in educating the blind, and the institution for idiots was not much heard of until it was moved to Waverley, where to-day it stands, with Dr. Fernald as its superintendent, with about 700 inmates and a waiting-list of 1300, Massachusetts having to-day in round numbers 5000 mental defectives of school age and less than 1000 cared for. On good authority, in the United States there are 100,000 of these defectives under twenty-one years, and less than ten per cent in any way looked after. There are twenty so-called " schools " supported or partly supported by states, where a conglomerate mass of defectives may be found, in most cases so badly classified that the name "school" is a misnomer; and in but one or two is the individual studied and developed according to its needs, as is done with remarkable results by Bourneville in France. England, or, rather, London, has special classes in connection with schools where much is done for the feeble-minded, 10% of the London school children are mental defectives. In Boston, the estimate is 1,000 such in our public schools; some put the number as high as 3,000. How many of our incorrigible girls and boys that we may find in houses of refuge, where they are half educated in letters and wholly unreached in morals, are sent into the community, later, the moral imbeciles they were in the beginning, only more powerfully armed for mischief? How many of our insane are really feeble-minded, wayward or neglected in their early training and at last conveniently housed in hospitals, after having wrought mischief, entered social relations, reproduced their kind, antagonized experts and lawyers, puzzled philanthropists, and in every possible way retaliated on their progenitors for their origin and on the community for their mis-

apprehension! And pauperism breeding other paupers, — what is it but imbecility let free to do its mischief? The brighter class of the feeble-minded with their weak will-power and deficient judgment are easily influenced for evil, and are prone to become vagrants, drunkards and thieves; how comes such a state of affairs?

The developing of mental defectives was conceived by a physician-educator who said, "Concerning the treatment of the feeble-minded, I would suggest that the experienced educator be called in, rather than the physician. The developing of the mind and the disciplining of the individual is more the province of the teacher than the physician."

Comparatively few physicians are educators; yet the work has fallen into the hands of the physician. In most of the institutions the school department is a secondary consideration; the *per capita* cost is a large factor, as to whether this or that institution is well run, — not what can we do for this individual child, regardless of cost.

The word "idiot" is misleading to the public at large, our latest medical authority classifying the idiot as a special form of insanity. Is it so? An insane brain, as I understand it, is a diseased brain, — not necessarily that of the idiot so-called. The words "feeble-minded" and "imbecility" are used to denote the idiot. Lately, "mental defectives" seems to be the favorite term. The public think of an idiot as a repulsive being to look at; "feeble-minded" and "imbecility" convey little idea to them, I find. Among the mental defectives, especially the high grades — who are by all means the most dangerous — may be found many attractive forms and faces, with real talent along certain lines. Did you ever hear of Blind Tom? He was feeble-minded in everything but memory, but he could hear the most complex music ever played and play it afterwards quite well; one could repeat the Lord's Prayer in Greek, and Blind Tom would repeat it right back and never know a word. At the New Jersey school, I knew a boy who had made a perfect model of a ship. You will be surprised at the results of many of these persons, if you comprehend what mind they have. Politics and a field for the physicians is a large factor in not allowing the work for mental defectives to be what it ought.

A word as to the causes of mental defect. Three thousand entrance blanks which I have gone over show tuberculosis to be the chief factor in the generation of idiocy. I find that the late Dr. Isaac N. Kerlin, in an essay on the "Classification and Causation of Idiocy," gives the histories of one hundred families, in each of which there was a case of idiocy. A careful examination of his tables shows that 145 members of these families, including parents, sisters, brothers and grandparents, were afflicted with pulmonary consumption. Statistics of the Royal Albert and Dareuth Asylums for mental defectives show that among the hereditary causes of 2,380 cases, consumption ranks the highest,— a percentage of 28.31, while insanity, epilepsy, intemperance, have a percentage of 16.47, 8.69 and 16.38, respectively. Dr. Langdon Down, physician to the Earleswood Asylum for Idiots, in his "Mental Affections of Childhood and Youth," says, "It appears to me that tuberculosis must be accepted as one important cause of idiocy; that it impresses special character thereon, while imparting a strong family likeness to the subjects of this class. It is no less clear to me that idiocy of a non-tubercular origin leads to tuberculosis. Whether this arises through the influences of the pneumogastric nerve, malassimilation of food, or defective innervation, it cannot be but regarded that the connection between these two troubles is by no means accidental, and that a due appreciation of this relation is necessary to those who would deal effectively with congenital mental lesions."

In a paper by Dr. Thomas J. Mays on pulmonary consumption in its relation to idiocy and imbecility, he says, "Any one who has made himself familiar with the history of feeble-minded children must have had his attention drawn to the prominent part which pulmonary consumption plays in the development of the diseases with which they are afflicted. Indeed, when one remembers that its influence in this respect is more conspicuous than that of insanity, epilepsy, or any of the other neuroses, one is forced to admit its exceeding intimate affiliation with the nervous system." "My own conviction, which grows with increasing experiences, is that consumption not only has a strong indirect relation to diseases which affect the nervous system, but is itself the result of a depreciated condition of the nervous system, and hence belongs to the family of disorders called the neuroses."

No one is surprised to find that insanity and epilepsy create a special liability to idiocy in the offspring, but it is certainly startling, especially in the light of its supposed bacillary origin, that consumption is more powerful in this respect than any other cause which is known to give rise to this trouble.

Exanthematous diseases furnish a rather high percentage in our tables of causation for feeble-mindedness.

A common condition with them is what used to be classed under that somewhat indefinite term, "scrofulous." The glands will become swollen very easily from comparatively slight irritative causes; they are subject to inflammatory eye diseases. Diseases, such as eczema, which is supposed to be non-contagious, will spread rapidly through a group of feeble-minded children. I know of two institutions where separate rooms had to be prepared and such cases isolated. They are very susceptible to cold, and will stand a high degree of heat, and, as I have shown, they readily fall victims of the bacillus of tuberculosis. Exanthematous diseases are generally more severe in their effect than in normal children. In an epidemic of measles, which took place in a large number of middle and lower grades of imbecility of which I had charge

in the wards some years ago, I was struck by the large percentage which developed complicating pneumonia and meningitis, as a rule fatal. Epilepsy very frequently complicates imbecility, sometimes preceding the development of mental weakness, more often occurring as an after-complication.

Deformities, sometimes due to paralytic contraction, sometimes not, are common. Various forms of cerebral paralysis (spastic palsies), accompanied often by choreiform and athetoid movements, are common among mental defectives, such cases falling into the large class constituting the paralytic type. Hearing is abnormally acute; they do not seem to see well, but training soon corrects this. The surgeon can do but little for the imbecile. The specialist finds a large field among this class. The removal of abnormal growths, as adenoids, the furnishing well fitted glasses, the orthopedic surgeon, may do much. Lack of muscular control calls for suitable muscular training. The military drill has met with excellent success. Speech-training is a very important factor in the development, calling for a specialist with a knowledge of laryngology, and also a well-trained elocutionist. Dr. Hudson McCuen, of the Polyclinic, at Philadelphia, has proven this with astonishing results, in a school I was connected with. Dr. A. W. Wilmarth, now superintendent of the Wisconsin Home for Feeble-minded, has probably made more post-mortem examinations on idiots than any other doctor in the United States, and has found that many cases of uneven mental development, where certain faculties seemed unusually developed, were due to small localized attacks of meningeal inflammation.

How is the idiot to be recognized? Judge Ashman of Philadelphia, in a paper on "A Medico-Legal Study of Idiocy," gives the best description of an idiot that I have seen. He says, "Hence an idiot [he uses this word to mean mental defect of all grades] while for all purposes of self-care may be absolutely impotent, may be taught to read and write. While the germs of all the human faculties are present, they operate on a minute scale, and when a careful training has educated them to the utmost, we still find that the balancing force is wanting, and that the idiot is hopelessly deficient in self-knowledge."

It is said, on good authority, that idiocy can be recognized in a new-born child by the lack of closing its hand firmly about any object laid in it. I have known this to prove true in thirty cases. Lack of co-ordination of the muscles, a peculiar gait apt to be like that of an old person, defective speech, lack of concentration, absence of the inquisitive sense, between the age of five and eight, a dull expression, lack of reasoning-power, speech may be wanting. Fernald says, "It is safe to assume that the child of six years without deafness or defect of the vocal organs who cannot talk is actually feeble-minded."

The diagnosis in the higher grades is not always quickly or easily made, while his capacity for self-care is greater, his capacity for public harm and his chance of danger and suffering is also greater.

The medical profession at large should be more fully convinced of the utility of education for these children. Such conclusion would save to comparative usefulness many helpless and hopeless lives. At present, even in families of means, imbecile infants are commonly allowed to grow to adult life in utter moral and mental neglect; and in many a case is the medical adviser responsible. The deaf-mute and the blind child enjoy increasing hospital and educational advantages; why not the mentally defective, peculiarly nervous and backward? Surely, with such results as are obtained by M. Bourneville, it is proven that more ought to be done for our feeble-minded.

I borrow from Dr. Eley's work, in which he has described at length the work of M. Bourneville in his medico-pedagogical institute at Vitry (Seine): Here are 250 children of the upper classes. The school embodies great comfort, healthfulness and convenience; it aims at the physical, intellectual and professional training of defective children; the methods have been borrowed everywhere from all schools, classical and special. He seeks "that which is"; "that which underlies in these children"; he will utilize his resources, however small, to train up most perfectly all the latent faculties he may find. The first principle is that the pupil is to be occupied continuously during waking hours with physical, hygienic and intellectual exercises, as many as will prevent idleness yet fall short of fatigue.

Through the influence of M. Bourneville, a special department numbering eight hundred was established at B——, where the same methods as at Vitry are carried out. At these schools a beginning is made with the education of sight and smell; walking and the muscular sense come next; then the larger object of awakening the attention and developing the instinct of preservation, the absence of which two signs makes a marked clinical symptom of idiocy. In the pedagogical work, the exercises are mutual and collective. The individual attention is appealed to, also the imitative faculty. Physical training — fencing, dancing, military exercises, gymnastics — is carefully adapted to each pupil's needs.

The surgeon finds his field in correcting deformities, and the physician administers his drugs for the ailments all children are heirs to. The proper medical work in these schools should simply follow the modern lines of specialization, and that physician called in who best knows how to reach the given defect or disease.

The best institution for the feeble-minded is not the one where the *per capita* cost is the least. That appeals to legislatures, because they do not understand the needs; and how can they, when affairs are as we find them in our legislatures to-day? Let public charity and state aid combine and give us schools for these least of God's

little ones, and thus aid greatly to stamp out crime, immorality, poverty, disease.

A few superintendents of our public schools are awakening to the fact that they have a duty to these peculiar children; that they need special training. Providence (R. I.), Philadelphia, Boston, and possibly one or two other cities, are slowly weeding their mentally defective children from those of normal minds, sending the unteachable ones to the state institutions to be cared for, and establishing schoolrooms for the teachable ones with small classes. Let them multiply. It is a step in the right direction. With time the types will be classified and home schools founded. Then progress will be made. One public school superintendent said to me, "This work calls for money, and where is it to come from?" The parents, state aid and public charity have a duty here.

The only justification for the expenditure of public money is the public good. That is, the good of the whole mass of the people. Any other theory of the expenditure of public money leads not only to extravagance and corruption, but necessarily to the confiscation of property. The assistance which we render to our fellow-man is charity. The assistance which the state renders is humanitarian; it is based solely on the good of society. It is the object of government to promote general welfare. We create and provide boards of health and make regulations to guard against disease. We quarantine a contagious disease, that the healthy may not suffer from contact; we have laws regulating employer and employed, governing workshops and factories, in order that the safety and well-being of our operatives be promoted; and upon the same principle which prompts the state to throw these safeguards around its citizens, it should protect them against the mental defectives. No state can afford to neglect a strict censorship over all classes which are mentally defective and are therefore likely to do harm. We live in an age of close contact, we all touch elbows, we are a part of a great social organism, and if one of us is ailing or defective, that whole organism is thrown out of joint.

There is not, to my mind, a more important problem before the public to-day than this of its mental defectives. Our dependent classes, through no fault of their own, infect the community in which they live, and infect society down along the generations to come; and society, whose duty it is to protect the general welfare, cannot neglect its obligation in this direction. I am of the opinion that every child (because the prevention of dependency must begin by treating the dependent in youth) should be examined by a competent commission, under state supervision, and if found to be mentally defective should at once become a ward of the state for proper training and care. This, surely, is more humane and merciful than to permit this child to suffer unnecessarily himself and to cause suffering to his fellows.

The feeble-minded which we have we must keep with us until they die, but they need not be allowed to bring other feeble-minded into the world. The fact that feeble-mindedness often is inherited supplies a solid foundation upon which to base restrictive and preventive measure.

OPERATIONS ON THE STOMACH, WITH REPORT OF CASES.

BY JOHN C. MUNRO, M.D., BOSTON,
From the Surgical Clinic, Carney Hospital, Boston, Mass.

(Concluded from No. 8, p. 216.)

No. LXXXV. Female, twenty-eight years old, referred by Dr. McGrath of Beverly, entered the Carney Hospital in December, 1903.

Two years ago she had complained of gas in the stomach and intestines, with distention relieved by eructation. These attacks came on irregularly and apparently had no reference to the food taken. At times there was nausea, but without vomiting or blood. There were pain and soreness in the epigastrium and she was badly constipated. Examination showed poorly digested food, a dilated and prolapsed stomach, with hydrochloric acid present.

At operation, by Dr. Bottomley, a sagging, dilated stomach was found, with normal pylorus. The mesocolon was adherent to the posterior wall. A gastro-enterostomy, with clamps and sutures, was made and the wound closed.

Patient was discharged in about three weeks, in good condition.

No. LXXXVIII. Female, thirty-five years old, referred by Dr. Dewis. She had had a pelvic operation of some sort six years before. Stomach trouble began about two years ago and was marked by the inability to eat any but the simplest form of food. After eating she complained of a lump in the epigastrium with pain lasting several hours. These attacks would be severe if she attempted to eat a hearty meal. There had never been vomiting. She complained much of eructation of gas one or two hours after eating. She had not lost weight. There was no history of blood in the stools. She was always constipated and had suffered from asthma for a number of years. During the attacks of gastric trouble she would shut off all food except a very small quantity of simple liquid, until she grew weak from starvation, when she would return to ordinary diet. Then at the end of two weeks or so the cycle would be repeated. Examination showed a sagging stomach, with the upper border a little above the umbilicus. Examination of the stomach contents showed complete achylia with prolapse and dilatation.

At operation, at the Carney Hospital, in May, 1904, there was found adherent to the lower abdominal scar a stretched-out prolongation of the omentum dragging the stomach downwards. This adhesion was ligated and cut. The stomach was found U-shaped and prolapsed; the lesser curvature lying one inch above the umbilicus; the pylorus, as well as the remainder of the stomach, appearing normal. The right lobe of the liver was prolapsed, with its edges nearly at the level of the umbilicus, the diaphragm being flattened and resting on the dome. A posterior gastro-enterostomy, with clamps and sutures, was done, the gastrohepatic omentum shortened, lifting the edge of the stomach nearly to its normal position. The slack round ligament of the liver was sutured to the under surface of the diaphragm, supporting the liver. Abdominal wound closed in layers.

No. LXVIII. Female, fifty-eight years old, transferred from the medical side of the Carney Hospital April, 1904.

She had had stomach trouble off and on for seven years, vomiting blood, without pain, the attacks coming on about every year. Three weeks before entrance she was troubled with gas, especially after eating, and distress. She had lost twenty-five pounds in the last year. She had been twice in an asylum with some mental trouble. In the epigastrium there was some tenderness on deep pressure. She had limited herself to the most simple diet for a number of years.

At operation the pylorus showed old scar tissue on the anterior wall and towards the duodenum. The opening was much narrowed and without induration. The patient was very fat and instead of doing a gastro-duodenostomy it seemed safer to do a posterior gastro-enterostomy in the usual way, with clamps and sutures. The wound was closed in layers. The patient did only fairly well after the operation, persisting in vomiting small amounts whenever attempts were made to feed her as the usual gastro-enterostomy patients are fed. So three weeks after the first operation the abdomen was reopened and the anastomotic opening was found free, easily admitting three fingers, but at the left angle there was a small point of adhesions between the stomach and the distal loop, close to the sutured edge, pulling the gut a little forward and making a slight kink, but apparently not sufficient to close the lumen even to a slight extent. The proximal loop was not edematous nor swollen. There was no sign of its being obstructed. Measurement showed that the distance from the edge of the suture to the jejunal origin was six inches, and as the gut lay in position there was no sign of loop or kink. The distal loop was negative. Palpation of the retroperitoneal portion of the duodenum showed no evidence of obstruction. The opening in the stomach was at the lowest level. The lumen of the pylorus was still narrow. Nothing elsewhere was found to account for the persistence in vomiting other than the small kink at the distal edge. However, entero-enterostomy was made, with clamps and sutures, and the wound closed. She made a good recovery, and in a short time was discharged in good condition, without having vomited, and gaining steadily and rapidly in every way.

No. LXXXIX. Male, fifty-five years old, was seen with Dr. Deacon of Milltown, N. B., in May, 1904.

Twenty years ago he had a severe attack of so-called inflammation of the bowels, since which time he had had a delicate stomach and had suffered much from dyspepsia. In the winter of 1902–03 he was ill for a long period. Cancer of the stomach was suspected from the symptoms. Hydrochloric acid was found present, and under careful treatment the patient improved and was fairly well during the summer. Relapse followed during the past winter, and an operation was advised. He had rarely vomited and only once or twice had there been any excessive amount. The abdomen had been tender in one spot in the pyloric region. He complained more of distention and gas than anything else, and at times, especially at night, the pain from this gas would be so severe that he was obliged to rest on his hands and knees. He had been very careful of his diet for years, and when the pain returned he would fast until he starved. He had lost weight and for years had been badly constipated.

At operation, at the Chipman Memorial Hospital, N. B., a moderately dilated stomach was found, while at the pylorus and adherent to the posterior abdominal wall was a tumor the size of a large horse-chestnut, extending along the duodenum for over an inch and a half, so that it did not seem practicable to attempt a pylorectomy. No lymph nodes were felt in the omentum or retroperitoneal space. A posterior gastro-enterostomy was made, with clamps and sutures, and the wound closed in layers. Towards the close of the operation he vomited some blood, and during operation the stomach showed some digested blood within its cavity.

A few weeks later the patient was in good condition and convalescing satisfactorily.

No. XCII. Male, fifty-five years old, referred by Dr. Wilder of Medfield.

For several years patient had had dyspepsia, with much gas and eructation, coming on in spells, lasting a month or more, with intervals when he would be free for a long period. The eructations came specially after drinking water. He had never vomited, but if he attempted to eat a full meal he would have pain, nausea and marked increase in gas formation. He had never vomited blood nor noticed black stools. He was very constipated and had lately had several attacks of typical mild appendicitis. Distress from the food would come quickly, with a feeling of fullness in the epigastrium, not always relieved by eructation, and even if expulsion of the gas did relieve the acute pain there would be a dull persistent ache. Recently he had lost a good deal of weight and had pain and soreness in the right hypochondrium.

Examination showed well-marked tenderness over the appendix, dilated stomach, with poorly digested food, hydrochloric acid, and slight tenderness over the pyloric region.

At operation, at the Carney Hospital, the stomach was found dilated, with a pylorus nearly closed, probably from an old ulcer, although that could not be established. There were no signs of malignant growth in any region. The gall bladder contained a calculus the size of a buckshot, but otherwise appeared healthy. A posterior gastro-enterostomy, with clamps and sutures, was made; with a short jejunal loop, and the abdominal wound closed. Through a second incision the appendix, which was obliterated through three quarters of its length, was removed. As there seemed to be no indications of trouble from the gall bladder it was left alone.

No. XCIII. Female, twenty-three years old, had had stomach trouble two years ago, lasting six months, pain coming on about one hour after eating and relieved by vomiting. Gastric pain not severe when the stomach was empty. She vomited blood once or twice in this attack. Eight weeks ago there was a similar, less severe attack. Four weeks ago there was epigastric pain again with vomiting, and three weeks ago she vomited fresh blood. As in the early attacks, the pain was relieved by vomiting.

At operation in May, at the Carney Hospital, a dilated, prolapsed stomach was found, the lesser curve being two inches above the umbilicus. Pylorus was slightly thickened and nodular at the upper anterior portion, but the lumen was patent. Enlarged lymph nodes were felt along the greater curvature. There were some adhesions found in the duodenum extending from the region of the bile ducts, but the gall bladder appeared normal. The duodenum was freed and a gastroduodenostomy (Finney) was done. Examination of the inner surface of the pylorus showed a small pin-head ulceration with some surrounding induration. Elsewhere the abdomen was negative. Abdominal wound closed in layers.

No. XCIV. Male, twenty-nine years old, referred by Dr. Deacon, of N. B. Six years bfeore I saw him in May, 1904; he had had indigestion with much vomiting lasting for six months. Eighteen months later he had a second attack lasting for ten

days, characterized by epigastric cramps and vomiting but without blood, or retained food. The vomiting persisted more or less up to a year ago. Never had been much gas from the first. In February, 1903, he vomited a little blood and was ill for four months. There was much vomiting three to four hours after his midday meal, consisting for the most part of bile. Since then he had had no severe attack, but considerable epigastric pain, gas and more or less vomiting and he had lost weight.

Examination showed the capacity to be two pints, some residue nearly digested after five hours, and the lesser border one inch above umbilicus.

He had derived no benefit from medical treatment at various places.

At operation at the Carney Hospital a dilated, prolapsed stomach, with the lesser curvature one inch above the umbilicus, was found. The liver was prolapsed to the level of the umbilicus. The gall bladder was found adherent to the deep portion of the duodenum, with a broad sheet of adhesions holding it against the posterior abdominal wall. The pylorus felt indurated and nodular as from a cicatrix, but the lumen was not much contracted. Enlarged lymph nodes were felt on the greater curvature. A gastroduodenostomy (Finney) was made. At one area on the mucous lining of the pylorus there was free bleeding whenever touched by the sponge. This area lay on the thickened portion of the pyloric ring, but there was no definite ulceration. The gall bladder, which was otherwise normal, after being freed, was sutured to the edge of the liver and the round ligament was sutured to the anterior wall to prevent further prolapse. Abdominal wound closed in layers. Discharged in good condition.

No. LXXXVII. Female, fifty-nine years old, referred by Dr. Dewis.

Ovariotomy seven years before I saw her. For four years she had had stomach trouble with temporary relief at intervals. For a year there had been burning in epigastrium and loss of weight. At the beginning of her dyspepsia for a space of six months all food except liquids caused distress.

Examination showed absence of hydrochloric acid, retained undigested food after eighteen hours, dilatation and prolapse.

At operation at the Carney Hospital in May, 1904, a moderately dilated stomach with the border two inches above the umbilicus was found. The omentum was firmly adherent by broad bands to the scar of the former operation, apparently tending to pull the stomach downwards. Pyloric opening normal. A gastroduodenostomy (Finney) was made. Examination of mucous membrane failed to show any ulcers. Gall bladder region normal. The omental adhesions were so extensive and deep that it seemed wiser not to attempt to disturb them. Abdominal wound closed in layers. Discharged in good condition.

No. XCV. Female, thirty years old, referred from the medical side, Carney Hospital, in June, 1904.

Before Feb. 12, 1904, at the time of her injury the patient had never been ill a day. On that date she was crushed and trodden upon in a crowd and was unconscious for three days. The day following injury she vomited bright blood and passed blood in her stool. For two months she was confined to bed and kept on very limited diet, vomiting blood nearly every other day besides passing blood several times in her stools.

Since April she had had many hemorrhages, coming on after pain in the lower lumbar region. When lying on her right side she complained of pain in the epigastrium.

While in the hospital she vomited coffee grounds and mucus, the vomiting containing free hydrochloric acid.

In addition to her abdominal injury she had various other injuries on the head, lower extremity, etc. There was also a marked element of neurosis present.

At operation the stomach was of about normal size and without visible evidences of ulcer. The pylorus felt normal and nothing abnormal in the duodenum or elsewhere could be found.

A posterior gastro-enterostomy, with clamps and sutures, was made, digested blood being found in the stomach. Abdomen closed in layers. Patient in hospital at time of report.

In conclusion, I should like once more to emphasize the fact that these cases have been collected and written up with only one or two main objects in view, namely, to present their clinical histories as they can easily be obtained by the general practitioner, and to illustrate, so far as can be done briefly, the gross pathological conditions as seen at operation. The paper has been written for this society, a large majority of the members of which are general practitioners, or at least not operating surgeons. To include the data that would appeal to the surgeon as well, would involve a much longer and a more tedious paper. Later, when the number of cases is larger, when the end results are better known, and after longer trial with the different operations, a more complete and satisfactory analysis can be made and the indications and contradictions with regard to surgical treatment can be more clearly demonstrated in the various types of lesions.

When we stop to consider that the cases reported in this paper represent those seen in one clinic, and referred by a small number of consultants, at a time when both the profession and the laity appeal to surgery as a last resort, we are justified in hazarding the belief that there must be a very large number of people in this part of the country who should at least be allowed to have surgical advice with regard to their symptoms of gastric and intestinal disorder.

But, as we have said before, how much surgery can do, and for what types of gastric and duodenal lesions it is the best treatment, time alone will tell.

Discussion.

Operations on the Stomach.

Dr. E. P. Joslin of Boston: The accompanying chart shows the results of operations upon benignant disease of the stomach at the Boston City Hospital and Massachusetts General Hospital, Jan. 1, 1898, to Jan. 1, 1904. It is taken from a paper now in course of publication by Dr. F. B. Lund and Dr. F. T. Murphy and myself. At a meeting of the Surgical Section of the Suffolk District of the Massachusetts Medical Society, held last winter, the question of operation upon benignant gastric diseases was discussed, and at its conclusion the suggestion was made that the results of these operations at the two large hospitals be combined and published. The writers are indebted to the chairman of the Surgical Section, Dr. F. B. Harrington, and the secretary, Dr. E. A. Codman, who arranged the meeting, for permission to use the Massachusetts

General Hospital statistics, and to the surgical staff of the Boston City Hospital for consent to record their cases. The writers further wish to express their appreciation of the kindness of Dr. Arthur T. Cabot, who read the manuscript before it was sent to the printer.

The reason for the publication of this chart at the present time is the firm conviction of the writers that gastric surgery is making such rapid progress in Boston that it is unfair to embarrass future statistics with those of the six pioneer years in this branch of surgery. Moreover, not long ago the medical aspect of ulcer of the stomach at one of these hospitals was critically studied by a physician and surgeon, and it seemed fitting that the surgical side of the question should be as impartially treated. The above paper showed that the immediate success attending medical treatment of ulcer of the stomach in Boston was far below that usually given in the literature. Fifty-five per cent of the patients were discharged well from the hospital in contradistinction to Leube's seventy-four per cent cured. The ultimate results were still worse and demonstrated that fifty-six per cent of the ulcer patients were either dead or had had stomach trouble referable to the ulcer since their discharge from the hospital. It is with *patients similar to this fifty-six per cent of medically unsuccessful cases that this paper deals.* While the results are not as favorable as have been elsewhere reported, they represent the facts. Furthermore they show the condition of the patient some time after the operation and not the immediate result alone.

The conclusions of the paper are as follows:

1. Results of operations in benignant disease of the stomach at the Boston City Hospital and the Massachusetts General Hospital.

JANUARY 1, 1898, TO JANUARY 1, 1904.

	Number of Cases	Deaths	Well	Re-lieved	Not Re-lieved	Secondary Operations
Hemorrhage,	10	10	0			1
Perforation,	18	13	5			2
Chronic Ulcers,	21	5	7	4	5	8
Pyloric Obstruction,	21	5	9	3	4	2
Acute Dilatation,	1	1	0			
Total,	71	34	21	7	9	13

2. Surgical intervention in gastric hemorrhage should be considered even before it is urgent, and the surgeon should jointly with the physician watch the course of the patient. Cases of gastric hemorrhage entering the accident room should be seen, as a rule, by a physician as well as a surgeon.

Operations upon females under thirty years of age should be most conservatively advised, since death under medical treatment is rare. This generalization, however, should not unduly influence consultants in a case of repeated hemorrhages threatening life, even in a patient below this age.

3. Mortality in operations for perforation of the stomach is chiefly dependent upon the length of time intervening between perforation and operation and the virulence of infection. To lessen the mortality house officers should report suspected cases simultaneously to the physician and surgeon on duty, or their substitutes, and should obtain permission for a possible operation from the patient or friends.

4. Patients with chronic ulcers of the stomach or strictures of the pylorus should be jointly watched by the physician and surgeon. The surgeon should know the patient before being compelled to operate. Postponement of operation after it is indicated is dangerous, owing to the possibility of hemorrhage, perforation and exhaustion.

5. Errors in surgical technic occurred, which in subsequent operations will presumably be avoided. Methods of operation were chosen, which in the light of the exeprience of to-day would be considered unsuitable. Together, these classes of cases account for about half of the deaths.

6. The seventy-one cases were operated upon by twenty-five different surgeons — an average of one case to each surgeon in twenty-five months. It is reasonable to conclude that the mortality would have been less if each surgeon had had more experience.

DR. F. B. LUND of Boston stated that it was a privilege to hear such a paper as that Dr. Munro had read, upon a subject of so much importance in the medical and surgical world. It seemed to him that, in this field, the greatest and most important advances in surgery at present are being made. Our knowledge of diseases of the stomach, and our ability to help, by surgical means, patients hitherto incurable, are rapidly advancing.

In regard to the table, of which Dr. Munro had spoken, he agreed with him that this table gave a very false impression of the mortality from diseases of the stomach. These operations were the early cases of a large number of men who were acquiring their experience in this class of surgery. With the knowledge of the pathology and surgical technic which the experience of these cases has brought, a greatly diminished mortality is to be expected in the future. It is easy, in reading the history of these cases, to detect errors in the interpretation of conditions, and in the technic of operations performed.

It has been pretty generally conceded by a large number of operators of experience, that the posterior gastro-enterostomy, as performed by Moynihan, and Finney's operation of pyloroplasty, are the methods which give the greatest relief with the lowest mortality in these cases.

The question of choice of methods to be used in individual cases is a broad one. The speaker's experience, and his study of the cases entering into this table, have led him to the general conclusion that, in cases where the pylorus is completely occluded by scar tissue, and is likely, therefore, to remain occluded, posterior gastro-enterostomy is the operation of choice. In cases where the obstruction of the pylorus is due to spasm from the presence of chronic ulcer, perhaps at some distance from the pylorus, cases in which, with a gastro-enterostomy, the pylorus would be likely to expand, allowing the gastro-enterostomy to contract, until a condition of things results from which the stomach gets proper drainage neither way, Finney's operation is perhaps indicated. However, the question of the best operation for various conditions is still *sub judice*. The question of the excision of the pyloric or ulcer-bearing area of the stomach, for ulcer of the stomach, is one that is interesting the surgical world to-day.

Dr. Lund then spoke of three cases of subacute perforation of the stomach. These occasions were signalized by epigastric pain, tenderness and spasm, soon subsiding, and not going on to general peritonitis, thus in contradistinction of perforation into the general peritoneal cavity. In these cases posterior gastro-enterostomy has been done without separating the adhesions which walled off the perforating ulcer or peritoneal cavity. By this procedure one avoids the difficult process of infolding a thickened and inflamed area of the stomach wall. Infection is avoided. The freest kind of drainage is provided, and the after history of these cases demonstrated that the ulcers healed rapidly under the internal drainage provided by the gastro-enterostomy, and the adhesions under the same conditions did not do any harm.

This technic, in the speaker's opinion, for every reason should be greatly preferred to the separation of the adhesions, thus opening up the ulcer, and infolding by suture of the perforations.

Dr. H. F. Hewes, of Boston: There can be no doubt that, in the advance in gastric surgery, medicine has become possessed of a new and very practical therapeutic measure for use in a very common branch of disorders, the diseases of the stomach. I am perfectly aware when I say this that the results in regard to gastric surgery are not yet all in. Most of our reports upon the subject are from surgeons who are apt to think more of the immediate result of the operation than of the ultimate result. Also time has not yet elapsed sufficient to test the mass of gastro-enterostomies which have been reported in preliminary records. Enough however has been proven to convince the medical mind that in gastric surgery we have a useful and fairly safe therapeutic method with a great future.

When and where to use this method is of course always a matter of judgment for the individual cases, but that it has a use, and that such possible use must be borne in mind by the physician in the consideration of each and every one of his cases of stomach disorder, is a fact which to-day admits of no doubt. When we consider the actual use of this new therapeutic method up to the present, we cannot but conclude, I think, in reviewing the field of fact and opinion, that the tendency is, for the physician, where the judgment rests with him, to use it too little or too late, for the surgeon under the same circumstances to use it too often and too soon. This of course is meant as a very general statement. There are many men in both ranks who are at one on the subject. This variation between the two branches is due, in fact, I think, to the difference in the experience of the two. The physician sees many more stomach cases than the surgeon — the mild and severe — and a great majority, 90% or so, get well under medical care. He looks upon a laparotomy as a dangerous operation, and rightly to a certain extent, and he prefers to take the chance of his case being among the 90%, unless the evidence is very strong against it.

The surgeon, on the other hand, sees as a rule only the serious cases, the 10% of uncured cases; he has not quite the same fear of a major operation as the physician, and he is for operation in a given case of doubtful character according to this experience. As a matter of fact, however, the fault with both physician and surgeon lies principally not in the difference of training or experience, but in an insufficient consideration in regard to diagnosis in the routine of cases which come to them.

If a full appreciation of the possibilities of diagnosis by the use of thorough methods, and a habit of applying these methods in all cases existed generally, a considerable number of cases which are now kept too long under medical care would come to the surgeon at an earlier date, and many cases with no indication for operation, save a doubt as to diagnosis due to ignorance of conditions present, would be spared unnecessary operation.

There is at some hands a tendency to decry expert diagnosis in stomach conditions, owing to the fact that the old rules promulgated before all facts were in, in regard to the association of absence of HCl, with carcinoma, have proved not to be infallible. The facts of the chemistry of the gastric contents make but a small part of the results of expert examination, and in connection with surgery, as a rule, a secondary part of very secondary importance. The facts which have the most bearing upon surgery of the stomach are those in connection with the motility of the organ, its size and the condition of its orifices. And these facts can always be determined by applying proper methods of diagnosis, and they should always be determined in every stomach case, however mild or however severe its type.

The findings may not always affect the question of operation in a given case, but they will frequently do so, and at all events we are in a better position in regard to treatment, medical or surgical, the more facts we have in. The number of cases treated medically in ignorance of the real conditions present would alone serve as an excuse for impressing this fact upon the physician, without the additional argument offered by the cases of carcinoma or ulcer which come too late to surgery. And the number of cases which I have myself seen operated upon without previous thorough investigation, where operation showed no condition present for which operation was indicated, serve as an excuse for impressing it upon the surgeon.

Dr. C. L. Scudder of Boston: It is a principle with which we all agree, that any surgical procedure must be done with precision and with speed and be adapted to the case in hand, in order that it may prove efficient. There is no procedure in surgery which demands such accuracy of technic as does the operation of gastro-enterostomy. Faulty technic may mean death of the patient.

I have been very much interested in the various operations upon the stomach which have been developing during the past few years. I have been interested in these operations from a physiological as well as from a purely surgical point of view. In a recent visit to the clinics of several surgeons in England and upon the Continent, for the purpose of learning the technic in use there in gastric surgery, I was very much impressed by the simplicity of most methods, but especially by the fact that, save in one clinic, the routine procedure in gastro-enterostomy is the posterior operation. As my contribution to this discussion of Dr. Munro's extremely interesting paper, I will describe and illustrate by means of lantern slides the various steps in the technic of a posterior gastro-enterostomy.

Dr. Scudder showed some lantern slides illustrating the various steps in the operation of a posterior gastro-jejunostomy, emphasizing the important details as the slides were shown.

Medical Progress.

REPORT ON OBSTETRICS.

BY FRANK A. HIGGINS, M.D., BOSTON.

TO PROMOTE LACTATION.

Zlocisti [1] argues that the infant after birth is as much dependent on the maternal organism for nutrition as during its fetal existence. It needs the milk as it needed the placental circulation before. He has applied to women the experience of stock raisers in regard to the value of cotton seed as a milk-producing substance for milch cows. The pulverized cotton seeds were given to nursing women when the milk seemed to be diminishing in quantity or quality, and the way the infants thrived on the milk produced in abundance afterward testified to the lactagogue efficacy of the "lactagol," as the powder is called. He urges the collection of statistics,

[1] Jour. Am. Med. Assn., Mar. 12, 1904, p. 744: Berl. klin. Woch., xli, No. 5.

showing the proportion of bottle-fed infants who have tuberculosis or cancer later, suggesting that the lack of breast nursing may prepare the soil for these diseases.

CICATRICES OF BREAST AND LACTATION.

In two[2] cases described, the breast had been the site of extensive burns previously. Lactation, however, proceeded normally in one patient, although the cicatricial areola was hard and inflexible, requiring softening and massage before the babe could nurse properly. The other patient did not nurse her infant, and as the milk was secreted, the breast became very painful. Under appropriate measures, lactation was suppressed as under normal conditions, without inflammation or gangrene of the burned breast.

The results in the first case correspond with the experience of the reporter, that even when the breasts are the site of old cicatrices, a child of a subsequent pregnancy may be nursed if the breasts are carefully attended to and given frequent massage to relax the adhesions.

PREGNANCY DURING LACTATION.

Church[3] says that the evil results of the overlapping of these two conditions are not generally known. He believes that were an inquiry made into the conditions arising from it, it would probably be found (1) that the suckling was or became a delicate child, that he at one or other stage of his development suffered from some affection of the nervous system, and that he was the mentally weak one of the family; (2) that during lactation the embryo was prematurely expelled from the uterus, or if it reached full time, that it, in many cases, did so with lowered vitality, and handicapped in some way or other for the race of life; and (3) that the mother's health was generally undermined for a longer or a shorter time. Seldom would it appear that the mother had blood and strength enough for the welfare of the trio.

INJURIES TO THE CHILD'S HEAD DURING DELIVERY.

Jardine[4] found that depressions of the skull caused by labor occurred in contracted pelves, and are caused by pressure of the promontory, but that they may also occur in normal pelves. Fracture may occur during delivery, and yet there may be no depression evident on a casual examination. Other serious injuries may occur, such as cortical or meningeal hemorrhage, traumatic keratitis, hemorrhage into the optic nerve, or anterior chamber of the eye. Subconjunctival hemorrhages are exceedingly common, even in normal labors, but they are of no consequence. If cortical and meningeal hemorrhages do not cause death, there is liability of permanent injury to the brain. Very little can be done in hemorrhages but to leave them to nature. If there is fracture, a trephine may be used, but in some cases where there is no fracture or depression, it is difficult, and, at times impossible, to locate the hemorrhage. In high forceps delivery one blade of the instrument usually lies over or near one of the eyes, and occasionally the eye is more or less injured. In difficult deliveries, the eye may be enucleated.

[4] Jour. of Obstet. and Gyn., Brit. Emp., June, 1903.

TREATMENT OF CRANIAL DEPRESSION IN THE NEWBORN.

Baumm[5] reports four cases, in all of which this condition was the result of difficult labor because of narrow pelves, the pressure of the promontory in three cases producing deep impressions in the skull, and in the fourth case causing fracture of the frontal bone. In the first case he thought of a corkscrew, and after sterilizing the instrument, bored into the bone, gave a pull, and suddenly the skull was rounded out, and the child's breathing and heart action improved for a time, but it soon died. Subsequent section showed no injury to the brain, but an internal cranial hemorrhage. The second case was a repetition of the first; in the third, however, the child lived and became healthy and strong. In the fourth case, as the skull was fractured, the corkscrew was more easily inserted, the skull was more readily restored to its normal shape, with complete recovery of the infant. In these cases it may be said that the child would have lived without the operation, but it is probable that there would have been permanent deformity, with defective brain action. Hence Baumm feels justified in recommending the use of the simple procedure mentioned in cases not too difficult, and always to strive for the removal of any skull depression.

PLACENTATION IN A UTERUS BICORNIS.

Herzog[6] obtained a bicornuate uterus removed at operation, with an early pregnancy in the right side. He was able to demonstrate from the specimen that the syncytium is of fetal origin, and that it is not developed from uterine epithelium. In the left half of the specimen he found that there was a fully developed decidua, in every respect identical with the decidua of the pregnant right side, so far as true decidual structures are concerned, with a distinct differentiation into a decidua compacta and a decidua spongiosa, and with the former containing enormously enlarged capillaries (blood sinuses), which were everywhere closed and not opening into intervillous spaces. Sections of the cervix showed that the muscularis was hypertrophied, with the individual fibres of the same size as the fibres of the muscularis of the body. A great tortuosity of the vessels was manifest by a great number of vascular lumina, seen everywhere in the cervical tissues. The mucosa showed a moderate degree of glandular hypertrophy with the surface of the mucosa thrown into folds. But the surface and the glandular epithelium were of the type found in the non-pregnant uterus. The interglandular connective tissue was quite

[5] American Medicine, July 4, 1903, p. 40: Zentralb. für Gynäk., May 9, 1903, p. 569.
[6] Am. Jour. of Obstet., June, 1904, p. 729.

vascular, and the interglandular connective tissue cells were fusiform and markedly enlarged in size, though not approaching the very large size of the true decidua cells, as found in the decidua on either side of the uterus duplex.

HYGIENE OF INFANCY.

Pinard [7] reviews the regulations decreed by the mayor of Villiers-le-Duc in regard to the hygiene of infancy by which the mortality has been reduced to zero. Every child born in the community during the last ten years is alive and well-to-day. The mortality had been 20 to 30.8% of the births during the previous decades for a century, with the exception of a single decade, during which the present mayor's father — likewise a physician — had been the incumbent, and devoted much attention to infantile hygiene. The regulations include one to the effect that every needy pregnant woman, married or not, must inform the mayor of her condition before the seventh month, and state the name of the midwife whom she wishes to have attend her. The midwife is then sent by the mayor to examine the woman, to ascertain that there is no albuminuria, no fetal or maternal dystocia, nor vicious presentation. She is paid from the public funds for each visit. If the midwife finds anything abnormal, the mayor is notified, and he sends a physician selected by the pregnant woman, o take charge of the case. Every parturient assisted by the community receives twenty cents a day during ten days after the confinement if she remains in bed. This amount is paid to her at the end of the ten days. If she gets up before this limit, she forfeits this sum. Other regulations specify points in regard to the feeding, fortnightly weighing of the infant, etc., and one promises a reward of forty cents a month, which is paid to every woman who has brought up a child to the age of one year in good condition, breast or bottle fed. This sum is paid to her at that time, computed for every month during the year that the infant has been in her charge.

THE INFLUENCE OF DIET IN PREGNANCY ON THE WEIGHT OF THE OFFSPRING.

Paton [8] says that it became evident in a study of the diets of the families of the poorer laboring class in Edinburgh, that poverty and the resulting deficiency in diet tell most severely in the early years of married life, when a number of young children have to be provided for, and he brings up these questions: How far does malnutrition of the mother during pregnancy influence the growth of the child? Do the children of the poor and badly nourished start life at a lower level than the offspring of those who are better fed? He cites Prochownick, who concluded that by restricting the diet of the mother, the size of the child may be markedly diminished, and his forty-eight cases in which, as a result of such regulation, the average weight of the child was: in 24 males, 2,960 gms., and in 24 females, 2,735 gms., the male children being 11% under the average, and the females, 14%. It seemed to Paton that the investigation of the question in the human subject is unsatisfactory, since so many disturbing factors come into play during pregnancy, and since it is difficult to determine whether the diminished size of the child is the result of less complete growth, or simply the result of premature labor.

Paton made a similar test with guinea pigs, one series of seven being fully fed and another kept on a low diet. The average weight of the offspring of the latter was 28% below that of the normal animal, and 10% less per gm. for the weight of the mother. He says that the observations, though few in number, are so concordant that they warrant the conclusion that the size of the offspring depends very directly upon the diet and nutrition of the mother during pregnancy. While this explains the easy labors among the healthy lower classes, and confirms Prochownick's conclusion that by dieting the mother, the children of rickety women may be so reduced in size as to be viable, it also probably helps to explain the very high infant mortality among the very poor. The infant starts life at a low level and readily succumbs to the hardships to which it is too often subjected. The nourishment of the maternal tissues seems to take precedence over the nutrition of the fetus. Had the embryo the prior claim to nourishment, we should find that in badly nourished mothers each gram would produce a greater proportionate weight of young than in well-nourished mothers. This is exactly the reverse of what occurs. The mother thus appears to pass on the surplus nourishment to the fetus, and the better the nutrition of the maternal tissues, the greater is the growth of the young in utero.

SUTURE OF RUPTURED PERINEUM.

Zweifel [9] says a medical man in Germany can be fined and imprisoned, besides having to pay compensation to the patient, for neglecting to suture a ruptured perineum. He mentions an actual case in which a medical man was charged with this neglect. He does not regard the position of the general practitioner as being worse in this respect than that of any other man, since there is no suggestion that he is responsible for the rupture. He is, however, responsible for the discovery of the rupture, and for an attempt to rectify it. The defence in this form of case may rely on an opinion that ruptures are capable of healing spontaneously. Zweifel says that he, at all events, has never seen a ruptured perineum heal up, that is, the torn surfaces were never approximated in those cases in which the healing was left to nature. Dealing with ruptures of the third degree, he say that every one will have the same opinion that spontaneous repair is impossible. Since the law will not allow for any lack of knowledge in a practitioner, this defence must

[7] Jour. Am. Med. Assn., Apr. 16, 1904, p. 1053: Bulletin de l'Académie de Médecine, lxviii, No. 11.
[8] Lancet, July 4, 1903, p. 21.
[9] Brit. Med. Jour., Jan. 16, 1904, Epit. p. 11: Deut. med. Woch., Jan., 1903, p. 10.

fail in the court. The next possible defence is that exhaustion on the part of the practitioner, or severe flow of blood, which could occlude the view of the parts might hinder the suture, but this is no excuse for not suturing it the next day. Another excuse offered in the particular case was that the practitioner did not feel justified in giving an anesthetic by himself, and he could not obtain the services of another practitioner. Zweifel points out that the injection of a 1% solution of cocaine will overcome the difficulty. The last defence offered was that an attempt to repair a rupture of the third degree would have been unsuccessful, and therefore he thought it wiser to advise the patient to have the repairing operation performed by a specialist after she had got over her lying-in. Zweifel thinks that there is good reason to advise primary suture, since this is much more likely to lead to good results than the second operation. He admits that it is frequently a failure on account of faulty methods, and to avoid this disappointment he gives a clear account of what he regards to be the best method of performing the operation, and of conducting the after-treatment.

PREMATURE DETACHMENT OF THE PLACENTA.

Gruning [10] says the precipitate detachment of the placenta at its normal site is a rare and dangerous complication of labor, ending almost invariably in death of the child, and often jeopardizing the life of the woman. The first indication of the trouble is usually a small hemorrhage which cannot be accounted for by a placenta previa or by laceration. The bleeding is followed by a profound anemia, out of all proportion to the slight external loss of blood. The uterus increases in size and assumes a round form. It is elastic, and makes palpation of fetal parts impossible. Death of the fetus takes place. The labor pains are feeble and favor further hemorrhage. As to treatment, the author is inclined toward active interference. In his five cases the forceps was used once, version once, in two the bag of waters was punctured, and dilatation by means of Braun's colpeurynter was resorted to in the last. Four children were born dead, two in a macerated condition. The one extracted after version survived. All mothers recovered.

BLOOD CHANGES AS AN INDICATION FOR INTERRUPTION OF PREGNANCY.

Mace [11] establishes an average standard for the blood findings in pregnancy, and then shows that variations from this standard may be an indication for the interruption of the pregnancy. The average of three healthy women, in at least the eighth month, was hemoglobin, 8%; red corpuscles, 4,493,000; whites, 9,640. Variations from this standard he has found are of serious import for the fetus as well as the mother. Besides pernicious anemia, the anemia from recurring hemorrhages entails serious injury to the blood. Pronounced polynucleosis indicates commencing infection, frequently starting in the uterus and causing the expulsion of the fetus sooner or later. It is not necessary to wait for this, if the condition is recognized early by the blood findings. Under the influence of slight but recurring hemorrhages, reds are swept into the circulation, immature and deformed.

EVIL RESULTS OF DEEP INCISION OF CERVIX DURING DELIVERY.

Hofmeier [12] remarks that voices have been raised in protest against the danger of hemorrhage from Dührssen's incision of the soft parts to facilitate delivery. No one, however, has published anything in regard to the remote evils of the procedure. In two cases recently, a subsequent childbirth proved fatal in one case, and without prompt intervention would have proved fatal in the other. The rigidity of the site of the former incisions resulted in rupture of the uterus wall just above the cicatrix. One patient had passed through two normal childbirths between the incisions and the last fatal birth. If the Dührssen incisions are deemed absolutely necessary, at least they should be made on the front and rear aspects, and not on the sides, near the large blood vessels.

Reports of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

ANNUAL MEETING AT ATLANTIC CITY, NEW JERSEY, JUNE 2, 3 AND 4. 1904.

FIRST DAY — THURSDAY, JUNE 2.

THE meeting was opened with a reception to guests, followed by the usual address of greeting by the president, DR. J. H. HARTMANN of Baltimore, Md., and then the association proceeded to the scientific session.

A CONTRIBUTION TO THE STUDY OF THE SECRETING MECHANISM OF THE NOSE.

By DR. J. L. GOODALE of Boston: After reviewing the literature of the subject, the writer called attention to two arrangements in the nasal mucous membrane for producing the nasal fluid, viz.: the glands and the intercellular spaces of the epithelium and the underlying basement membrane. Up to the present time it had not been determined whether serous glands were present in normal nasal mucous membrane, in addition to the mucous glands, or not; and the writer found that in normal cases the mucous membrane of the respiratory portion of the nose contained both serous and mucous glands in association. He then called attention to the changes produced in the glands of the mucous membrane, and in the canals of the basement membrane, in different pathological conditions, such as chronic inflammations characterized by increase of secretion, chronic atrophic inflammations and vasomotor rhinitis.

Chronic inflammations with increased secretion showed a heightened activity of the mucous glands, irrespective of the secondary changes in the other con-

stituents of the tissues. Atrophic inflammations, with tenacious fetid secretion, showed a complete disappearance of the canals of the basement membrane, while the mucous and serous glands showed a much diminished, but still distinct, degree of activity. In the vasomotor rhinitis there was found a striking increase in the looseness of structure of the epithelium, and in the number and size of the canals of the basement membrane, — an alteration distinctly out of proportion to the moderate increase in the mucous and serous glands.

The normal secretion of the nose consisting, as it does, of mucus and serum from the glands and a large quantity of watery fluid coming by transudation through the canals of the basement membrane and the intercellular spaces, we can readily understand the changes in the character of the secretion in the above-mentioned conditions by the changes found in the secreting organs, that is, the glands and the canals of the basement membrane.

NASAL HYDRORRHEA; REPORT OF A CASE.

By Dr. J. Edwin Rhodes of Chicago, Ill.: The writer detailed the differential diagnosis between the cerebrospinal rhinorrhea and nasal hydrorrhea; defined the latter as a copious flow of watery fluid from the nasal mucous membrane, continuous or intermittent, usually unilateral, though sometimes bilateral, accompanied by other symptoms, such as headache, insomnia, cough, sneezing, and other nervous phenomena. Of the two generally advanced theories as to cause, — (1) that it is a neurosis of the trifacial nerve in the nasal mucosa, and (2) that it is one of the symptoms of a general neurasthenic condition, — the writer inclined to accept the latter.

He then detailed a case in which many different therapeutic measures were tried with no effect, until nitrate of silver was used, 60 gr. to the ounce, after which the discharge ceased in three or four days, with no return. The application caused a violent headache, lasting four or five days.

In discussion, Dr. Swain of New Haven gave it as his opinion that *any* agent, used to the required degree, would have given the same result, as it was the violent systemic disturbance and reaction which caused the cure.

OBSERVATIONS ON THE THERAPEUTIC VALUE OF MEDICATED OINTMENTS IN CERTAIN AFFECTIONS OF THE NASAL CHAMBERS.

Dr. A. W. MacCoy of Philadelphia read a paper with the above title, in which he deprecated the too free use of washes in the nose as inconvenient, unpleasant and often harmful, and made a plea for the use of oils, and especially thin or soft ointments, as menstrua for administering medicaments to the nose, preferring petroleum in some form to anything else.

SOME REMARKS ON THE INTRA-NASAL SURGERY OF TO-DAY.

Dr. J. N. Mackenzie of Baltimore read a paper with this title. The general tenor of the paper was that of protest against many of the radical methods now in vogue. He thought that they were pursued by some operators with a most indiscriminate zeal, and were calculated to bring the modern surgery of this region into disrepute.

One reason for this *furor secandi* was the fact that the interior of the nose would stand a great deal of mutilation without dangerous reaction; but this was no justification of the course so often followed.

The author believed in thoroughness when operations were justified, but he could not accept as valid some of the arguments advanced to justify many of the operations done at the present time on the nose and accessory sinuses.

He felt that relief from the present condition of affairs must come through a better education of the rising generation of laryngologists.

THE ETIOLOGY AND DIAGNOSIS OF OZENA, AND ITS RELATION TO PULMONARY TUBERCULOSIS.

Dr. Clement F. Theisen of Albany, N. Y., read a paper with the above title, a continuation of a paper on the same subject, published in January, 1904, in the *Albany Medical Annals*, with reports of forty cases. He discussed the usually accepted points of diagnosis, *i. e.*, presence of decomposing, foul secretions and crusts, and atrophy of the mucous membrane, and considered the etiology, particularly with reference to sinus disease and acute infectious diseases, such as measles, scarlet fever and diphtheria, and then its relation to pulmonary tuberculosis. His conclusions may be summarized as follows:

(1) Sinus disease probably causes ozena in a certain percentage of cases, or at least may be considered a strong predisposing cause.

(2) Suppurative processes in the accessory sinuses, as shown by Pearce's investigations, are frequently present in certain of the infectious diseases of childhood, particularly scarlet fever, measles and diphtheria, and for this reason these diseases must be considered as at least possible etiological factors of ozena.

(3) That while a certain percentage of cases *are* caused by sinus disease, this is not sufficient to explain the pathogenesis of the whole clinical picture of ozena.

(4) The large number of ozena patients having pulmonary tuberculosis would certainly point to the nasal condition as a strong predisposing cause for the development of the tuberculous condition.

In discussion of the paper, Dr. T. J. Harris of New York said that in a considerable number of cases of ozena he had found a very small percentage with any sinus complication; and in regard to the relation between ozena and tuberculosis, he had found in twelve cases only one tubercular case, that being a tubercular larynx. He referred also to Hamilton's statistics as very different from those of Dr. Theisen, showing very few cases of tuberculosis in conjunction with ozena.

Dr. C. G. Coakley of New York also stated that he had found the association of sinus disease and ozena very rare.

Dr. J. Payson Clark of Boston spoke of the large number of cases of ozena and atrophic rhinitis found in a series of one hundred cases of tubercular laryngitis which he had examined, as compared with the same conditions in a similar number of cases coming to the clinics with other conditions not tubercular.

Dr. J. E. Newcomb of New York referred to a series of cases, seventy in number, of tuberculosis, with not one case of ozena.

Dr. H. L. Swain of New Haven said that he had not found any concurrence of sinus disease and ozena, but that he considered it reasonable that tuberculosis should be associated with ozena, since the latter condition presents such a good chance for the growth of all kinds of bacilli.

Dr. William E. Casselberry of Chicago expressed the opinion that a conclusion on this subject could not be reached until the term "ozena" was either abandoned or more exactly defined, with which opinion Dr. Theisen, the author of the paper, in closing, thoroughly agreed.

A STUDY OF THE FATAL RESULTS OF OPERATIONS UPON THE NOSE AND THROAT.

DR. FRANCIS R. PACKARD of Philadelphia regarded it as surprising that so few fatalities followed in this class of operations, considering the frequency with which they were done. He presented tabulated lists of the fatalities recorded in literature. He found 26 fatalities from anesthesia, — 24 from chloroform, one from a.c.e. mixture and one from ether, the last apparently from bronchitis. Chloroform deaths occurred with special frequency in those patients who presented the "status lymphaticus." Of deaths due to causes other than the anesthesia, he found 22. Of these, fourteen were from hemorrhage after removal of tonsils and adenoids. Other causes were meningitis, from use of perchloride of iron for epistaxis; purulent lepto-meningitis following operation by external incision for the removal of nasal polypi and orbital tumors; meningitis following cauterization, with galvano-cautery of the middle turbinate; meningitis following probing and injection of the lachrymal canal; meningitis after removal of an exostosis, and sepsis and exhaustion following tonsillotomy.

FOUR UNUSUAL TUMORS IN THE NASO-PHARYNX.

This paper, by DR. WALTER F. CHAPPELL of New York, was a report of four cases of tumor, all remarkable for their size, and one for its character and source. One was a very large polyp, projecting into the naso-pharynx; two of the others were very large pharyngeal tonsils, filling the whole naso-pharynx and extending down into the pharynx, and the fourth a large pedunculated growth springing from the left tonsillar region, near the Eustachian tube. In character, as stated by Dr. Jonathan Wright, it was "essentially nothing more than an enormous exaggeration of the so-called mulberry hypertrophies, very frequently seen, in a less advanced stage, at the posterior end of the inferior turbinated bodies. The most remarkable and unique feature of this growth, in this situation, is the occurrence of lymph nodes."

The operations for removal were all through the mouth, and simple.

(To be continued.)

ANNUAL MEETING OF THE MAINE MEDICAL ASSOCIATION

WALTER E. TOBIE, M.D., SECRETARY, PORTLAND, MAINE.

THE fifty-second annual meeting was held in Portland June 1, 2 and 3, in the Common Council Chamber, of the City Building. The President, Dr. Augustus S. Thayer of Portland, presided over the three days' sessions which were largely attended.

The treasurer, Dr. Arthur S. Gilson of Portland, read his report showing a balance in the treasury of $1,696.85, this amount being about half as much as was shown in the report of 1902. Dr. Gilson called attention to several large sums paid out within two years, notably $1,000 appropriated to the Maine Sanatorium for Consumptives and over $800 expended for the semi-centenary celebration. Dr. Gilson felt that the financial condition was on the whole satisfactory, and with the increasing membership looked for a still better showing next year.

DR. BIGELOW T. SANBORN, superintendent of the Maine Insane Hospital at Augusta, read a paper on the "Care of the Feeble-Minded." Dr. Sanborn made a strong plea for the establishment of a school for the feeble minded in Maine. He spoke of the courtesy shown by the Massachusetts authorities, in receiving patients from Maine at the Waverley Institution, but showed that the small number accommodated there was but a fraction of the total number who should receive this form of training.

The following resolutions were presented and adopted by vote of the association:

"*Resolved*, that the members of the Maine Medical Association believe it to be for the interest of the people of Maine that children and young adults who are feeble-minded should be, so far as possible, segregated, instructed, and diverted by useful employment. For this end, the experience of other states has demonstrated the value of state schools for the feeble-minded. Therefore, it is further

"*Resolved*, that the establishment of such a school in Maine is commended to the attention of our state legislature."

DR. WALTER E. TOBIE gave notice of a proposed change in the Constitution abolishing the office of corresponding secretary, and showed that it was a useless office inasmuch as all of the work was done by the recording secretary.

FIRST DAY — AFTERNOON SESSION.

DR. F. L. DIXON of Lewiston, first vice-president, acted as chairman while the president, Dr. Augustus S. Thayer, delivered his address.

DR. THAYER extended a hearty welcome to the members and reflected pleasantly on the semi-centenary celebration of last year. Commenting on medical education he said: "Much hard and good work has been done, and much has been accomplished, but often after long years of waiting. Reforms are usually slow in coming and require persistent and long continued effort. By this persistent effort, largely due to this association, medical education has made rapid strides in our state. Fifty years ago our medical school had five professorships, and these five professors gave what instruction was given in the school. Three years of study, including two courses of lectures of three months each, was required for graduation. Now the school has fourteen professors, six instructors and four demonstrators. Four years of study is required, including four courses of lectures of eight months each. By this persistent effort we now have on our Statute Book a law enabling those teaching anatomy and surgery to pursue their courses without becoming criminals. But to accomplish this it took over forty years."

Regarding reorganization: "The committee to whom was referred the subject of organization of the profession throughout the state upon the general plan proposed by the American Medical Association will make its report. I anticipate that this report will favor the new plan, but whatever this report may be, it must come before you for final action. I trust you will all be prepared to give it that careful consideration that the importance of the subject demands. Should the report favor the new plan, and should the association vote to ratify the same, it would mean a complete reorganization of our association. Let us not forget that under our present organization this association is an independent body, subject to no dictation from outside sources. What it may become, should you decide to make the change, is an important matter for you to consider."

DR. THAYER urged that action be taken toward securing legislation making vaccination compulsory, and recommended that a committee be appointed for that purpose.

DR. WALTER E. ELWELL of Togus presented the report of the Committee on Legislation regarding Victims of Drug Habits. The committee presented a

proposed law for voluntary commitment, which required that general hospitals receiving aid from the state should be obliged to receive such patients and maintain for this purpose a suitable room or rooms.

The report was accepted and a committee appointed to secure, if possible, the proposed legislation.

DR. JAMES E. KEATING of Portland read a paper on "Fallacious Kidney Disease." DR. ALFRED MITCHELL, Jr., of Portland read a paper on the "Treatment of Prostatic Hypertrophy." DR. GEORGE H. COOMBS of Waldoboro read a paper on "Appendicitis in Country Practice." DR. JAMES A. SPALDING of Portland read a paper on "Medical Mistakes."

FIRST DAY. — EVENING SESSION.

DR. H. L. BARTLETT of Norway presented the report of the visitors to the Maine Insane Hospital. DR. WELLINGTON JOHNSON of Augusta read a paper on the "Three Stages of Labor." DR. GEORGE P. MORGAN of Dover, N. H. read a paper on "Neurasthenia."

SECOND DAY. — MORNING SESSION.

DR. SETH C. GORDON of Portland read the report of the Committee on Organization in accordance with the plan proposed by the American Medical Association. The report favored the plan and called attention to its advantages, but after a lengthy discussion it was not adopted. The feeling seemed to be that the present organization was so satisfactory that no change was indicated, but in order that the members might act intelligently, it was voted that the committee be continued, with instructions to furnish the details of the plan to each member.

The objections presented were: That the State Association would lose, to a great extent, its independence; that it would greatly increase the amount of clerical work and add expense; and that county societies might admit members ineligible under the present code of ethics of the state association.

DR. GALEN M. WOODCOCK of Bangor read a paper on "Rectal Alimentation." DR. LANGDON T. SNIPE of Bath read a paper on "Life Insurance Examinations." DR. W. M. SPEAR of Rockland read a paper on "Sub-Acute Intestinal Obstruction."

SECOND DAY. — AFTERNOON SESSION.

DR. G. M. WOODCOCK of Bangor read the report of the visitors to the Eastern Maine Insane Hospital.

The election of officers then took place as follows: President, Dr. F. L. Dixon, Lewiston; 1st Vice President, Dr. R. D. Bibber, Bath; 2d Vice-President, Dr. A. H. Stanhope, Dover; Corresponding Secretary, Dr. A. H. Sturtevant, Augusta.

Censors: Drs. H. F. Twitchell, Portland; D. M. Hayes, Henderson; S. P. Warren, Portland; C. E. Williams, Auburn; George C. Parker, Winthrop.

The following officers were previously elected for a term of years: Recording Secretary, Walter E. Tobie, Portland; Treasurer, Arthur S. Gilson, Portland.

DR. WALTER E. TOBIE read his report as necrologist, recording thirteen deaths within a year, including two charter members.

DR. WALTER E. ELWELL of Togus read a paper on "The Oblique Incision and Single Flap Method of Inferior Chiloplasty." Dr. Elwell's paper was illustrated by diagrams, and he presented for inspection two patients on whom he had operated by this method. DR. H. B. PALMER of Farmington read a paper on "Some Surgical Diseases which the Physician must Recognize." DR. B. L. BRYANT of Bangor read a paper on "Leucemia with Special Reference to the Spleno-Medullary Form," which was illustrated by charts.

DR. C. C. O'BRION of Groveton, N. H., was introduced as delegate from the New Hampshire Medical Society.

The session adjourned at 4 o'clock for the annual dinner at Riverton.

SECOND DAY. — EVENING SESSION.

DR. A. K. P. MESERVE of Portland, secretary of the State Board of Registration, presented a paper on the "Medical Registration Law," which was read by DR. CHAUNCEY R. BURR of Portland. After reviewing the results of registration in Maine and commenting on the reference to reciprocal registration: "Under the rules resulting improved conditions," Dr. Meserve said, "as adopted and approved July 31, 1901, any person who has been examined and registered by this board, can register in New Jersey, Illinois, Michigan, Ohio, Wisconsin, and probably in New Hampshire and Texas, without further examination if they are graduates of accepted schools.

"Thus it will be seen that reciprocal registration in other states is made possible for those examined and registered by state boards, but in what status does it leave the survivors of the 1,021 graduates of medical schools, who were practicing in the state when the law went into effect and who embrace the foremost physicians and surgeons of the state to-day? Should any of us desire to move to another state, an examination stares us in the face, not an easy nor pleasant grind for one who has been out of school for ten or fifteen years and engaged in busy practice.

"To meet this class most of the states mentioned have adopted another rule which reads: 'That a certificate of registration, or license issued by the proper board of any state, may be accepted as evidence of qualification for reciprocal registration in any other state, provided the holder of such certificate had been engaged in the reputable practice of medicine in such state at least one year, and provided that the holder thereof was, at the time of such registration, the legal possessor of a diploma, issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date of such diploma was prior to the legal requirement of the examination test in such state.' This qualification the Maine Board has not yet voted to accept. But ought we not to do it? It seems to me that with the proof of good moral character and professional standing required by our rules for all reciprocal registration, that no possible harm could come to the people of the state or the profession thereby."

It was voted that the chair appoint a committee on legislation as regards registration to confer with the State Board of Registration.

The Committee on President's Address reported favorably on the recommendation that restrictions be placed on the payment of money for purposes, other than the legitimate running expenses of the Association, and the recommendation that steps should be taken to secure legislation governing the control of water supplies, but took no action on the recommendation regarding compulsory vaccination.

DR. FREDERICK C. SHATTUCK of Boston delivered the annual oration, the subject of which was "ANOMALIES OF THYROID SECRETION.[1]"

The Association extended a vote of thanks to Dr. Shattuck.

THIRD DAY. — CLOSING SESSION.

The closing session was devoted entirely to business.

The Board of Censors made its final report recommending:

That the next annual meeting be held in Portland,

[1] See Journal, June 30, 1904, p. 689.

on the first Wednesday, Thursday, and Friday in June, 1905.

That the election of orator be left to the next Board of Censors, with power.

That the president and secretary have power to fill vacancies occurring in delegations to other State Societies.

That applications for membership received this year and not acted upon be referred to the next Board of Censors.

The president appointed as a Committee on Medical Registration: Drs. F. C. Thayer, Waterville; W. P. Giddings, Gardiner; B. L. Bryant, Bangor; F. W. Searle, Portland; George R. Campbell, Augusta.

The Committee on Legislation relative to Venereal Diseases was continued for another year.

The Association voted thanks to the President, Business Committee, Entertainment Committee and City Government.

Recent Literature.

Le Malattie dei Paesi Caldi, Loro Profilassi ed Igiene; con un' Appendice, la Vita nel Brasile. DOTT, CARLO MUZIO. p. 562. Milano. 1904.

This volume is one of the Hoepli series of scientific manuals, and contains the collated experience of Surgeon C. Muzio of the Royal Italian Marine, with reference to the diseases of hot climates. In addition to the many cuts with which it is illustrated, there are several geographical charts showing the prevalence of the plague, malaria, beri-beri, leprosy, anchylostomiasis, and other diseases.

The following general classification of diseases is adopted in the work:

General diseases, localized diseases (including those in which the presence of a specific germ has been proven, those in which the existence of such a germ though alleged, is not accepted, and those in which the cause is unknown), diseases and lesions produced in man by animals and parasites of hot countries, poisons, common infectious and other diseases, and sunstroke. To these the author adds a chapter upon the hygiene of hot climates, having special reference to clothing, food, water, habitations, etc.

An appendix is added in which are presented the author's observations upon those plants, insects, reptiles, and other objects which are in any way related to health and life in Brazil.

Surgery of Paralysis. By A. H. TUBBY and ROBERT JONES. London: Macmillan & Co.

That the writers have been able to present to the public such an excellent little book as this, written upon a large subject with so succinct and clear statements of the methods of treatment of the paralytic affections, is due to their thorough familiarity with the subject as well as to their sound judgment and excellence of good sense. The book is not only the best in the English language upon the subject, but the form is admirable, the subject being well presented and in a way interesting to the general practitioner as well as to the surgeon. The progress in many branches of surgery is now so rapid that the printer's ink is hardly dry in a publication before newly collected facts often necessitate the revision of the statements of any writer. The recent evidence presented by German surgeons, Lange and Hoffa and others, of the value of subperiosteal transplantation as well as the use of silk sutures (referred to in the work under consideration) need at present more full consideration than seemed necessary when the work was first written.

Aseptic and Antiseptic Preparation and Treatment of Emergencies after Abdominal Surgical Operations. By GEORGE WACKERHAGEN, M.D., Ex-President Brooklyn Surgical Society, etc., etc. New York: E. R. Pelton. 1904.

This brochure of forty-four pages has been prepared by its author for the purpose of obtaining a ready reference hand-book for the use of junior assistants and nurses. It is not claimed that it suggests anything new as regards symptom or treatment; it is rather a practical system of preparation for abdominal operations, and an outline of treatment of possible post-operative emergencies. Among these, nausea, vomiting, tympanites, secondary hemorrhage, intestinal obstruction and peritonites are considered.

The book is so classified that specific details can be referred to by number, thus avoiding the necessity of writing full directions for a nurse or assistant each time such directions are required. The character of the text is personal and local, but the design of the book is excellent, and it is clearly, concisely and systematically presented.

Fatigue. By A. Mosso, Professor of Physiology in the University of Turin. Translated by Margaret Drummond, M.A., and W. B. Drummond, M.B., C.M., F.R.C.P.E. New York: G. P. Putnam's Sons. London: Swan Sonnenschein & Co., Ltd. 1904.

In this volume of the Science Series Professor Mosso of the University of Turin offers a somewhat popular exposition of his theory of fatigue, the book now appearing in English for the first time, translated by Margaret Drummond and W. B. Drummond of Edinburgh. The text, which occupies 334 pages of small octavo form, is entertainingly written in a style so popular that it may be read intelligently by persons wholly unacquainted with the scientific aspects of the subject. The book is already known to students of physiology, and it is, therefore, not necessary here to enter into detail regarding the subject matter beyond drawing attention to the fact that it takes up the various physiological theories of fatigue largely on an experimental basis, and makes certain practical applications to school work and matters of ordinary hygiene in a way which should commend it to persons interested in educational matters as well as to physicians.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 1, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

PROTRACTED AND RECRUDESCENT INFECTION IN DIPHTHERIA AND SCARLET FEVER.

ONE of the most perplexing questions with which physicians and health officers have to deal in the management of infectious diseases is that of "return" cases of scarlet fever, and diphtheria, many of which appear at first sight to be due to the return of cases from isolation hospitals to their families.

One of the ablest of English health officers has contributed a very carefully prepared paper upon this subject, in which he gives the results of ten years' experience in an English town.[1] Some of the most important points in connection with this inquiry are stated in the following summary:

1. Cases of protracted and recrudescent infection are relatively infrequent, and represent only a small percentage of the total cases of these two diseases.

2. Such cases are oftenest associated with nasal and aural discharges, though not always. Accurate and detailed statistics on this point are wanting. "In my experience the proportion in which there are no mucous discharges is small, but their occurrence is undoubted."

3. The absence of this information indicates the necessity for more accurate records of cases of protracted and recrudescent infection, and for this purpose Newsholme presents a model form of record.

4. The occasional occurrence of such "return" cases emphasizes the necessity for post-isolation supervision of patients, whether treated at home or in hospital. This supervision must be medical and should be carried out officially. In Brighton scarlet fever patients are not allowed to return to school until four weeks, and diphtheria patients not until six weeks, after they have been released from home or hospital isolation.

5. A study of the "return" cases enumerated in Dr. Newsholme's paper indicates that in most instances the rhinorrhea, which is oftener than any other morbid condition associated with protracted infection, was already present when the patient was first isolated, or appeared soon afterward. This fact has an important bearing on the origin of "return" cases. It suggests the belief that a condition determining protracted infectivity may have been similarly present from the first in the infecting patients, in whom no obvious mucous discharge occurred.

6. If it be assumed that a morbid condition of the naso-pharynx is a necessary condition of protracted infectivity, do this morbid mucous membrane and its crypts act as a continuing incubator of scarlatinal or diphtherial germs originating from those which caused the patient's illness, or do they act merely as a suitable storehouse for germs derived from other acute patients in the same room — a storehouse which can only be emptied by one or more weeks' absence from acute patients? The author believes that the specific micro-organisms of these diseases remain in crypts of the naso-pharynx, which act as active "incubators" of them. This applies to cases continuously infectious. In those cases in which infection temporarily disappears, to recur under the influence of a catarrh or some traumatism, etc., it may be supposed that the specific micro-organisms have been lodged, and at least partly incarcerated in the follicles, and possibly in deeper lymphatic tissues or glands.

7. There is definite evidence that in some instances infection has become dormant, to be again roused into activity by various circumstances, as by the disturbance caused by the cessation of isolation, possibly in connection with baths at the time of discharge, or at a later period by a catarrh or other means tending to lower personal resistance.

8. Observations show a close analogy between the phenomena of protracted and recrudescent infection in scarlet fever and in diphtheria. In both diseases infection is occasionally exceptionally prolonged. From a clinical standpoint it must still be regarded as an open question whether protracted infectivity is more common in one of these diseases than in the other. In both diseases infection occasionally recrudesces.

[1] Protracted and recrudescent infection in diphtheria and scarlet fever. By A. Newsholme, M.D., F.R.C.P., Medical Officer of Health, Brighton, England. Public Health, Aug., 1904, p. 690.

This may occur either in the form of a definite relapse, having all the clinical features of the disease in question; or, more commonly, the only accompaniment of recrudescent infection is the recurrence of a mucous discharge, and even this indication of the possibility of recrudescence may be absent.

Newsholme considers the long accepted view of the profession, that the desquamating period is the most infectious stage of scarlet fever, as erroneous. "We now know," he says, "that desquamating patients may, as a rule, safely be sent home in the sixth, or even the fifth, week of their attack of scarlet fever, if they have no mucous complications. Some other cause must, therefore, have given rise to the widespread conviction that cases of scarlet fever were frequently infectious to the very end of desquamation. Such cases really occurred, or the conviction would not have arisen. Doubtless they were the cases of persistent or recrudescent infection which now exercise our minds in relation to hospital administration. But when this conviction was formulated, there were no isolation hospitals for scarlet fever."

THE SEWING-MACHINE AND GYNECOLOGICAL AFFECTIONS.

SOME twenty years ago we were told impressively by the most eminent teachers of the diseases of women that the sewing-machine was the root of much gynecological evil; woman could use her legs for any other purpose without danger to her health so long as she did not run a sewing-machine. Of late years the profession has heard less and less of this theory which has finally become, as is so often the case with the decadent theories of the profession, the property of the laity.

Now comes Nussbaum with an article [1] on the influence of sewing-machine work on health, in which he undertakes to show from statistics and his own experience that the position at the machine and the constant use of the legs are liable to cause congestion and consequent inflammation of the female genitalia.

When a plausible theory has once secured a firm place in the mental *armamentarium* of the unprogressive it often requires a severe shock to dislodge it, and, failing that shock, it remains to serve as a guide to thought and action for many a day. That uterine diseases are common among women who use the sewing-machine is an undoubted fact; that they are less common in the large shops where the machines are operated by steam or electric power than in those where the motive power is the foot or in the shops without machines where women sit working all day in constrained attitudes has not been demonstrated.

Bicycling, playing the organ or pianola, running, walking, swimming, dancing and tennis, in all of which the legs come into play vigorously, are generally admitted to be beneficial to pelvic disorders. No facts have been adduced to prove that the troubles attributed to the sewing-machine are not in reality due simply to prolonged sedentary occupation without proper exercise to offset it.

Reasoning from *a priori* grounds it would seem as if the movements of the muscles of the lower extremities would bring blood to the legs and feet and to that extent away from the pelvis; surely this is the province of exercise of the body as a whole, to increase the activity of the heart, quicken the circulation, and send the blood to the muscles and extremities and away from the internal organs. Sitting in one position for hours at a time, often in unhygienic surroundings and with tight clothing, is conducive to a sluggish circulation, and to passive congestion.

We may advise our patients to rise and change their positions as frequently as possible, to loosen their corsets, to sit erect and breathe deeply, and, most important of all, to take active exercise in the open air, if only a little gymnastics, for a short time before and after meals; at least, let us relegate the sewing-machine bogey to the limbo of disuse.

[1] Wiener Klinische Rundschau, xviii, No. 17, 1904.

A HEALTH EDUCATION LEAGUE.

AN organization with the foregoing title has recently been formed, with its office in Boston, and having as its object "the prevention of avoidable disease by the education of the people to high standards of personal and public health." The president of the society is Dr. D. A. Sargent of Cambridge; vice-president, Dr. H. S. Pomeroy; secretary, Rev. George H. Cate; treasurer, A. L. Darrow. Among the directors are several well-known instructors in sanitary science and members of sanitary organizations.

A primary object of the League appears to be to supplement the teaching of hygiene in professional and technical schools by education of the people, since "sanitary progress depends upon society's appreciation of health rather than upon technical knowledge of disease."

Much of the work already done in public hy-

giene is neutralized by the ignorance of the people as to what constitutes pure air, pure water, pure food, and healthful environment, and hence the indifference of the public as to the importance of enforcing public sanitary measures. The League seeks to reach the people through the public schools, the churches, clubs, gymnasiums and other institutions, if suitable lectures, booklets and circulars are provided.

There is undoubtedly a wide field of usefulness for such an organization, and it is to be hoped that it will receive hearty support. Its first publication, a tract entitled "Hints for Health in Hot Weather," is a decided success. It is not only an up-to-date publication scientifically considered, but also a sample of terse, intelligible Anglo-Saxon, absolutely freed from technical terms, and well adapted to popular requirements.

The League is in urgent need of funds for conducting this important educational work and for publishing its literature, not only in English, but in other languages, also for securing competent persons to arouse and instruct the people in the most needy places, and for other similar purposes. It appeals especially to the medical profession, since it is more closely in touch with the people than any other profession or class. Physicians have exceptional opportunities for observing the habits and social condition of the people with regard to sanitary matters, and can materially aid the society, not only with financial aid, but with intelligent co-operation.

Contributions may be sent to Mr. A. L. Darrow, treasurer, 113 Devonshire Street, Boston, who will promptly receipt for the same.

MEDICAL NOTES.

Cameron Prize. — It is stated that the Cameron prize of Edinburgh University has been given to Professor Finsen of Copenhagen for his work in practical therapeutics.

Appointment to Chair of Tropical Diseases. — It is announced from Washington that Surgeon P. A. Lovering has been ordered to Washington to take the new chair of tropical diseases at the Navy Medical School. This chair has been founded in view of the duties in tropical countries now more and more devolving upon the navy and marine corps.

Medical Department, University of California. — Hereafter the medical department of the University of California is to be closely affiliated with other departments of the university. This progressive step is in line with the general tendency observable throughout the country of bringing medical instruction into the same category as other departments of education.

Bequests. — By the will of Alexander C. Hutchinson, whose death occurred in New Orleans Dec. 7, 1902, an estate of nearly one million dollars was left for charitable and benevolent purposes. It has recently been announced that the Eye, Ear, Nose and Throat Hospital, St. Ann's Asylum and the House of the Good Shepherd, all of New Orleans, have received $20,000 each. The remainder of the property has been left to the medical department of Tulane University.

A Centenarian. — Dr. C. F. H. Wilgohs died Aug. 26 in Akron, Ohio, at the reputed age of one hundred years and eight months. He was born in Denmark in 1803. His father was a physician and served in the German army, and the son for a time did likewise. He also enlisted in the war for Polish independence and was many times wounded. Later he came to America, and for the greater part of his life has practised medicine in Ohio.

BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon Aug. 31, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 51, scarlatina 11, typhoid fever 47, measles 1, smallpox 0.

Anthrax at Burlington, Vt. — It is reported that anthrax is prevalent on a farm in Burlington, Vt., a number of cattle having died of the disease. A case has also appeared in a man who had to do with these cattle, and his condition is regarded as serious. It is suspected that the origin of the anthrax was Australian wool used in the neighborhood.

Boston Mortality Statistics. — The number of deaths reported to the Board of Health, for the week ending Aug. 27, was 152 against 180 the corresponding week last year, showing a decrease of 28 deaths, and making the death-rate for the week 12.90. The number of cases and deaths from infectious diseases was as follows: Diphtheria, 35 cases, 2 deaths; scarlatina, 9 cases, no deaths; typhoid fever, 42 cases, 1 death; measles, 4 cases, no deaths; tuberculosis, 41 cases, 16 deaths; smallpox, no cases, no deaths. The deaths from pneumonia were 7, whooping

cough none, heart disease 14, bronchitis 1, marasmus 5. There were 16 deaths from violent causes. The number of children who died under one year was 51, under five years 61, persons over sixty years 30, deaths in public institutions 60.

NEW YORK.

A SMALL BABY. — As an offset to the enormous infant recently born to a young Italian woman in Manhattan, we now hear of the smallest baby ever received in any like institution, which on Aug. 7 was brought to Dr. Couney's incubator at Coney Island by Dr. C. S. Patterson of Brooklyn. This remarkable infant, a male, weighed, it is stated, just one pound and six ounces and measured eleven and a half inches in height, and it is claimed that no record exists of a child of its size having lived more than a few hours. In addition to having the most vigilant care, it is being given frequent inhalations of oxygen, on account of the feebleness of its circulation, and Dr. Couney regards it as having a fair chance of living.

REDUCTION OF INFANT MORTALITY. — The New York Health Department has formulated, according to the *Medical News*, the following instructions regarding ordinary nursery hygiene and sanitation, in the hope that thereby the infant mortality may be decreased:

First — Nurse the baby, and nurse it regularly, about every three hours. If you cannot nurse the baby, consult your own physician or send to the Department of Health for a physician. *Second* — Do not give the baby condensed milk. *Third* — Never use the loose milk sold in grocery stores as food for the baby. *Fourth* — Never give the baby raw milk in warm weather. *Fifth* — Use only bottled pure fresh milk, properly prepared and sterilized, and feed the baby at regular intervals, about every two and a half or three hours. *Sixth* — In the morning prepare and sterilize enough milk to last the baby during the day and until the next morning. Cover each bottle and place on ice after sterilization. *Seventh* — See that the nursing bottles and nipples and all dishes used to hold the milk are kept absolutely clean. Wash these utensils in hot soap suds and then rinse in scalding water each time before using. *Eighth* — The water that is used to dilute the milk must be boiled. *Ninth* — Send to the Department of Health for a circular telling just how the milk should be prepared and how the baby should be fed and cared for, or notify the Department of Health that you want a trained nurse to show you how to prepare the food. *Tenth* — Send at once to the Department of Health or for your own physician if the baby becomes ill. Stop giving milk during the illness of the child, and give the milk only when the physician directs it.

Obituaries.

PROF. KARL WEIGERT.

IN the recent death of Prof. KARL WEIGERT of Frankfurt a. M., Germany loses another of her most brilliant and productive medical men. The night before his death he was apparently in his usual condition of health, and evidence of serious illness had not been suspected. The cause of his death proved to be disease of the coronary artery with thrombosis.

Weigert was born at Münsterberg in Schlesien on the 19th of March, 1845. His parents kept the first inn of the town, which became in its way a center for the region round about. Weigert never lost interest in the remembrance of these early days and the simple life associated with them. Later he studied in Breslau, particularly under the physiologist Heidenhain, and later in Berlin where DuBois, Virchow, Langenbeck, Traube and other distinguished men were teaching. His first assistantship, which was interrupted by the Franco-Prussian war, was in 1868 in the Breslau Pathological Institute. After the campaign he worked in Lebert's medical clinic and devoted his time to the study of practical internal medicine until Cohnheim offered him the position of first assistant in the department of pathology at Breslau. Thereafter he became a devoted follower of Cohnheim, and in 1878, when Cohnheim was called to the professorship of pathology in Leipsic, Weigert soon followed as "extraordinary" professor. At Cohnheim's death, which occurred about six years after his assumption of the Leipsic professorship, although fully fitted for the position through work already accomplished and through capacity for further research, Weigert was denied the succession, owing to his race. This was a period of much discouragement, and, as one of his biographers has said, for a time it appeared that he might be obliged to return to the "misery of general medical practice." In 1885, however, he was called to Frankfurt as director of the Senckenberg Institute, where he has since carried out the investigations which have placed him in the front rank of his calling.

Weigert's earliest important publication was on the subject of the staining of bacteria, published in 1871, and later supplemented by a similar article in 1875. Later, an important article on "Nephritis" appeared from his pen, and also one on "Vein Tuberculosis and its Relation to Miliary Tuberculosis." After his call to Frankfurt his attention was more particularly turned to problems relative to the nervous system, and especially to methods of staining. The myeline sheath stain, published in 1885, followed by his fibrin and elastic fiber stains, and finally his monograph on a new method of staining normal human neuroglia, mark a progress in the study of the nervous system and in microscopic technique in general which few other men have accomplished. In 1896, he read an important paper on new attitudes towards pathological anatomy, and since that time, although not

publishing widely, has kept in closest touch with the advances in pathological anatomy. It was proposed this coming spring, on the occasion of his sixtieth birthday, to collect his widely scattered publications as a memorial volume.

In personality Weigert was genial and endeared himself to the students who gathered at his laboratory from various parts of the world, and particularly from the northern countries of Europe. Many Americans also found a hospitable welcome and opportunities for work under his general direction. Unlike many of his contemporaries he seldom entered into controversy. He wrote only when he felt that he had some special message to convey; he had small patience with the many attempts to modify his methods under the guise of originality, and in general preserved the broad-minded and dignified attitude toward his work and his profession which in this time of competition is not always attained. His loss will be deeply felt, not only at the institute in Frankfurt which he had done much to develop and to whose reputation he had materially added, but also to the wider circle of investigators throughout the world who have been indebted to him for methods of research which have made possible many valuable contributions to medical literature.

WILLIAM RICE PRYOR, M.D.

Dr. William Rice Pryor, a well-known New York surgeon, died in St. Vincent's Hospital, New York, on Aug. 25. He was the youngest son of Roger A. Pryor, ex-Justice of the New York Supreme Court, and at the time of his death was in his forty-sixth year. Dr. Pryor was graduated from the College of Physicians and Surgeons in 1881. Since 1884 he has been professor of gynecology in the New York Polyclinic Hospital, visiting gynecologist to St. Elizabeth's, and consulting gynecologist to St. Vincent's Hospital. He wrote copiously on medical subjects, was a member of many medical associations and enjoyed a large practice. He is said to have been particularly considerate of the poor and to have extended his charity to them with liberality and wisdom.

Miscellany.

MEDICAL WOMEN IN RUSSIA.

By an imperial ukase recently promulgated in St. Petersburg, according to the *British Medical Journal*, women who wish to practice medicine are placed on exactly the same footing as men. The way is freely opened to them to obtain not only a license to practice, but the degree of Doctor of Medicine. Women who have obtained the title of doctor at a foreign university are admissible at once to the Russian state examination. For admission to the Institute for the Education of Medical Women, the possession of a leaving certificate of a recognized girls' school and the passing of a "not too severe" entrance examination are required. The candidate must not, however, be a Jewess, and she must not be less than nineteen nor more than twenty-eight years of age. A Jewess can be admitted only if the number of co-religionists in the Institute does not exceed three per cent of the whole number of students. Applicants for admission to the Institute who have neither home nor relations in St. Petersburg will be compelled to live in a hostel specially established for the purpose.

AN ANTIVACCINATIONIST ANSWERED.

In one of Dr. William Everett's entertaining contributions from England to the Boston *Transcript* (Aug. 27), he narrates the following anecdote, which was told him by an English physician:

A "conscientious objector," being brought before a magistrate to account for refusing to have his child vaccinated, pleaded that he was conscientiously opposed to the process. The magistrate, in a blustering way, insisted on his detailing the grounds for his objections. "Why," said the objector, "I had one of my elder children vaccinated and he has turned out pretty nearly an idiot." "Well," said the justice, "I never heard that vaccination operated to prevent hereditary complaints."

THE REGIUS PROFESSORSHIP OF MEDICINE AT OXFORD.

The *Lancet* comments as follows upon Dr. Osler's Oxford appointment:

Prof. William Osler has been appointed by the King, Regius Professor of Medicine in the University of Oxford in succession to Sir John Burdon Sanderson who has recently resigned the post. We heartily congratulate the Crown upon their choice and no less heartily do we felicitate the University upon adding to the number of their professors so brilliant an exponent of science. It will be remembered that at a meeting of Oxford medical graduates which was held in London on Jan. 5 a resolution was passed, "that in the opinion of this meeting the Regius Professor of Medicine should be a physician who is representative of medicine in its widest sense." Everyone will allow that the new Regius professor fulfills this requirement to the uttermost. As a teacher Professor Osler has had a very wide experience, having filled the chair of medicine at McGill University, Montreal, his first *alma mater*, at the University of Pennsylvania, and at the Johns Hopkins University, the position which he now quits for Oxford. He is the author of the best textbook of medicine of the day, one which enjoys a large circulation among practitioners and students alike, and he is universally recognized as one of the foremost exponents of modern medicine. It is an open secret that there promised to be some difficulty in filling the chair vacated by Sir John Burdon Sanderson, and at the meeting of Oxford medical graduates to which we have referred it was held by resolution that the Regius professor "ought to be a man who could be accepted as the leader and representative in Oxford of the medical graduates and one to whom they would with all confidence give their loyal support." Oxford has now obtained just such a man. In Professor Osler's hands the University may be sure that the medical school will progress upon learned, practical and dignified lines.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, AUGUST 20, 1904.

CITIES.	Population Estimated, 1904.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from				
				Infectious diseases.	Acute lung diseases.	Diphtheria and croup.	Typhoid fever.	Diarrheal Diseases.

Deaths reported, 3,097; under five years of age, 1,279; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,202; acute lung diseases 194, consumption 310, scarlet fever 10, whooping cough 18, cerebrospinal meningitis 29, smallpox —, erysipelas 5, puerperal fever 7, measles 11, typhoid fever 57, diarrheal diseases 710, diphtheria and croup 45.

From whooping cough, New York 2, Chicago 7, Philadelphia 5, Baltimore 1, Boston 3. From measles, New York 7, Philadelphia 1, Baltimore 1, Boston 2. From scarlet fever, New York 5, Philadelphia 4, Baltimore 1. From cerebrospinal meningitis, New York 24, Baltimore 1, Boston 1, Worcester 1, Somerville 1, Watertown 1. From typhoid fever, New York 20, Chicago 4, Philadelphia 11, Baltimore 10, Providence 1, Boston 5, Cambridge 1, New Bedford 1, Newton 1, Waltham 2, Melrose 1. From erysipelas, New York 1, Chicago, 1, Providence 1, Boston 2.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending Aug. 6, the death-rate was 19.8. Deaths reported 5,785; acute diseases of the respiratory organs (London) 54, whooping cough 95, diphtheria 46, measles 118, smallpox 7, scarlet fever 20.

The death-rate ranged from 6.5 in Southampton to 37.6 in Liverpool; London 19.6, West Ham 30.7, Brighton 12.4, Plymouth 14.6, Bristol 11.9, Leicester 17.4, Nottingham 23.5, Bolton 15.1, Manchester 25.5, Salford 23.5, Bradford 21.2, Leeds 21.7, Hull 23.4, Sheffield 20.0, Cardiff 13.3, Rhondda 23.0, Wigan 22.4, Merthyr Tydfil 17.2, Smethwick 7.7.

METEOROLOGICAL RECORD.

For the week ending August 20, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

RECENT DEATHS.

JOHN MCCLARY STEELE, M.D., M.M.S.S., died in Worcester, August 1, 1904.

ALONZO CARTER WEBBER, M.D., M.M.S.S., died in Cambridge, August 5, 1904, aged seventy-eight years.

HARRIET RAWSON GOODRICH, M.D., M.M.S.S., died in Salem, August 23, 1904, aged thirty-five years.

SOCIETY NOTICES.

NEW YORK AND NEW ENGLAND ASSOCIATION OF RAILWAY SURGEONS. — The fourteenth annual meeting of the New York and New England Association of Railway Surgeons will be held at the Academy of Medicine, New York City, Nov. 17, 18, 1094, under the presidency of Dr. C. G. J. Finn, of Hempstead, Long Island.

NORTHERN NEW YORK MEDICAL ASSOCIATION AND THE ST. LAWRENCE COUNTY MEDICAL SOCIETY. — These two associations will hold their meeting Oct. 18, 1904, at Ogdensburg, N. Y., the Northern New York Medical Association holding session during the afternoon and the County Society during the evening of the same day.

QUARTERLY MEETING, RHODE ISLAND MEDICAL SOCIETY. — The Quarterly Meeting of the Rhode Island Medical Society will be held in the Hall of the Y. M. C. A., Providence, on Thursday, Sept. 1. Meeting of the House of Delegates at 10 o'clock. General session at 11 o'clock.

AMERICAN ROENTGEN RAY SOCIETY. — The fifth annual meeting of the American Roentgen Ray Society will be held at the Louisiana Building, 911 North Vandeventer Ave., St. Louis, Mo., Sept. 9, 10, 12 and 13.

TRI-STATE MEDICAL SOCIETY OF ALABAMA, GEORGIA AND TENNESSEE. — The sixteenth annual session of the Tri-State Medical Society of Alabama, Georgia and Tennessee will be held at Chattanooga, Tenn., Oct. 12, 13, 14, 1904, under the presidency of Dr. F. B. Sloan of Cowan, Tenn. The headquarters will be at the Read House.

Addresses will be delivered by Dr. William J. Mayo of Rochester, Minn, and Dr. A. J. Ochsner of Chicago.

BOOKS AND PAMPHLETS RECEIVED.

Clinical Urinology. By Alfred C. Croftan, M.D. Illustrated. New York: William Wood & Co. 1904.

Annual Report of the Board of Health of the Department of Health of the City of New York for the Year ending December 31, 1902. New York: Martin B. Brown Co. 1904.

The Practice of Obstetrics. Designed for the Use of Students and Practitioners of Medicine. By J. Clifton Edgar. Second Edition, Revised. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1904.

A Practical Treatise on Genito-Urinary and Venereal Diseases and Syphilis. By Robert W. Taylor, A.M., M.D. Third Edition, Thoroughly Revised. Illustrated. New York and Philadelphia: Lea Brothers & Co. 1904.

Friedberger & Fröhner's Veterinary Pathology. (Authorized Translation.) Translated and Edited by M. H. Hayes, F.R.C.V.S. With Notes on Bacteriology by Dr. G. Newman, D.P.H. Vol. I. London: Hurst & Blackett, Ltd. Chicago: W. T. Keener & Co. 1904.

WHAT SHALL WE DO WITH PATIENTS HAVING PULMONARY TUBERCULOSIS?*

BY FREDERICK I. KNIGHT, M.D., BOSTON,

Consulting Physician to the Massachusetts General Hospital, to the Sharon Sanatorium and to the Free Home for Consumptives.

The modern method of treatment of pulmonary tuberculosis may be said to have had its inception more than fifty years ago. It then began to be appreciated that great benefit came to certain consumptive cases by a generous diet and outdoor life; and horseback, camp and other outdoor means came to be quite generally recommended by the profession. While the results were good in some cases, they were not usually curative, because the gravity of the condition was, as a rule, recognized late, and also because no restriction was put upon the amount of physical exercise which the patient should take, and many a one rode or tramped himself to death.

The plan of keeping patients under control in an institution was carried out as early as 1839 by Dr. George Bodington of Warwickshire, England, who took a house near his own for this purpose, and gave practically the same treatment as is in vogue to-day, including fresh air day and night. He was followed by Brehmer in 1859, and later by Dettweiler, the latter of whom insisted on the importance of rest rather than exercise in most cases. Koch's discovery of the bacillus gave a decided encouragement and impetus to the treatment of pulmonary tuberculosis, inasmuch as it showed that many cases, cured in their incipiency, were really tuberculous, which might otherwise have been considered doubtful.

We may consider the modern method of treatment to be fresh air, generous diet, often complete rest, and expert supervision, the latter being especially important.

How can we best secure these to our patients?

In considering this question it will be well to divide the patients into three financial classes: (1) Those who are abundantly able to pursue any course recommended without regard to expense; (2) those who can afford only limited time and money; (3) those who must depend entirely on charity.

It will be well also to divide the cases, somewhat arbitrarily, of course, into three pathological classes: (1) The incipient, (2) the somewhat advanced, and (3) the far advanced, and to consider the question what to do with a patient of either of the three financial classes according as he falls into one or other of the pathological classes. I will not attempt to draw a strict line of classification in either regard; the majority of cases will fall naturally into one class or another financially and pathologically, and it would be impossible to discuss at this time those which may fall near the border line.

We will consider first the patient who has incipient pulmonary tuberculosis, and who is abundantly able to do anything or go anywhere to recover his health. Now in such a case it is not necessary to be positively sure of the diagnosis of a pulmonary affection by the crucial test, *i. e.*, the discovery of Koch's bacillus in the sputum; of course we examine for it, but those cases which are, in my opinion, doubtful, only suspicious, may for the sake of safety be treated as if the diagnosis was positive. These cases which are doubtful may be briefly mentioned here. They may show debility, and may or may not cough, with or without expectoration (if present, free from bacilli), but on examination of the chest, there may be found localized at the apex of the lung a few râles. These are, perhaps, the most suspicious of the doubtful signs, and if we know they have developed recently in connection with cough and perhaps fever, they are pretty sure to prove tuberculous, due, perhaps, if there is no sputum, to tuberculous pleuritis, as was long ago insisted by Leaming. Then there are the various slight modifications of the percussion note and respiratory murmur. Of course, it is not necessary to tell the expert that slight relative dullness at the apex of the right lung is normal, yet it is not infrequently pointed out to me by physicians as important.

A great deal of stress is laid upon the variations in respiratory murmur, the prolonged expiration (it must be strictly borne in mind also that the expiratory murmur at the right apex is relatively considerably longer than at the left in health), and the interrupted or deferred inspiratory murmur, but these signs are not enough for a positive diagnosis, neither is the shadow or impaired expansion, as shown in the x-ray picture, or any other sign indicative of slightly increased density; they are suspicious, but not diagnostic. The tuberculin test, even if it could be relied on to denote the presence of tubercle in the body, does not show that it is pulmonary. It may be asked if it makes any practical difference, if tubercle is present in the body, where the process is located. It certainly does, for tuberculosis of the respiratory tract is usually much more serious and requires more prompt and radical treatment than that of other parts; in fact, in some other regions it seems frequently to remain latent for a lifetime. I am willing to concede a probable diagnosis of tuberculosis of the respiratory tract from a combination of early signs and symptoms, but I do not think we are justified in classifying such cases as positively tuberculous without the presence of Koch's bacillus in the sputum. I think they should be put into a class by themselves as "probable incipient cases." Be it understood, however, that I approve of treating such doubtful cases as tuberculous.

There is another class of cases, seldom met, perhaps, but which does exist, and which may be mentioned in this connection. I refer to patients who present no clinical signs or symptoms of respiratory tuberculosis, yet in whose expectoration, tubercle bacilli are accidentally discov-

* Read at the meeting of the American Climatological Association at Philadelphia, June, 1904.

ered. If this condition is persistent, I do not hesitate to say that patients having it should be put at once on restorative hygiene. I recall one such case in which my advice was rejected, in which after a few years the patient, one of the first financial class, abundantly able to take care of himself, broke down with serious pulmonary tuberculosis.

What shall we do with a patient with incipient disease who is willing and able to pursue any course we recommend?

I have said that the essentials of modern treatment are fresh air, day and night, generous diet, often complete rest, and expert supervision. Shall we try to give him these at home? Even if his home is well situated in the country, it is better not to do so, in fact it is well-nigh impossible to carry out the fresh air treatment at home. He may sit on the piazza for an hour or two, but very few will be found to sit out alone all day while the family are gossiping around the fireplace inside. Then, of course, the temptation to do business or other things, now prejudicial, is ever present. Such a patient should go to a community of such patients, where a hygienic mode of life is the rule. Here he can have his own house and family if he likes, but the general tone of the place will make him follow the directions of the physician, and he will find plenty of company in the outdoor life. Many of these communities have started up about sanatoria because the location of the sanatorium is supposed to be especially selected for its salubrity, and because patients can here have the advice of the experienced physicians of the institution. As a rule, a patient of the first financial class can have more comfort and luxury in his own house, but occasionally we meet one whom it is hard to control, and who will do better in a sanatorium. When he has learned the habits of such a place, he may, if he recovers, carry out many of them in his own home.

It is not my purpose at this time to consider special climatic conditions with reference to bronchial irritability or the general nutrition and vitality of the patient, though this is important, very important in some cases, but not entitled to so much consideration since it has been shown that tuberculous patients may recover by means of outdoor life in any climate. Still, the same climatic conditions do not suit all patients, and when possible they must be considered with reference to each individual case.

Of transcendent importance, however, is skilled supervision. Many a life has been sacrificed of patients dispatched to a climate where outdoor life is pleasant, who followed their own inclination in everything, and thought their mere presence in the region was all that was necessary, even if half their time was spent in hotel barrooms, and though they did ride horseback with a body temperature of 103° F.

In the present state of our knowledge we should commit our patient, if possible, to an expert of sufficient experience and wisdom to refrain from unnecessary medication, especially vaunted specifics, but who has sufficient knowledge of general medicine to discover and treat underlying conditions which may have predisposed to the disease, and which may still be aggravating it.

The same course should be pursued with a patient of the first financial class who comes in the second pathological class, though, of course, he must plan for a much longer stay. If a patient of the first financial class falls into the third (or far advanced) pathological class, the question will be whether he should be made as comfortable as possible at home, or make a new home in a better climate for the rest of his life. This depends a good deal on the temperament of the patient, his love of home and old ties, his sensitiveness to temperature changes, and also on the possible existence of an irritable bronchitis, which may be constantly aggravated in a harsh climate, and be very much soothed in a milder one.

I shall never forget the gratitude of one patient who went away knowing he would not return, but grateful for the comparative comfort of his last days.

What shall we do with a patient of the second financial class (of moderate means) and of the first pathological class (incipient)?

It is hardly necessary to repeat that all incipient cases are better treated away from their homes. A good private sanatorium is the best place for most patients with incipient disease who fall into the second financial class. It would usually be well that it should not be very distant from home, in order that the patient may be visited by his family occasionally, and also return at times, with the consent of the authorities, for necessary business. A patient of moderate means with far advanced disease, as a rule, had better husband his resources for comfort at home.

And now comes the question, the most important, perhaps, for the welfare of the community: What shall we do with the third financial class, the patients dependent on charity? Sanatoria and hospitals are what is needed for these patients, of all classes pathologically, and the institutions should be absolutely free and not hampered with small fees, or a declaration of poverty. A beginning has been made, but the ideal condition will not be realized until a poor tuberculous patient in any stage of the disease can have free hospital accommodation. And I believe that the isolation and control and treatment of all such patients, often ignorant and careless, will be an economy, as has been often pointed out before, to the state or city which provides for them.

If the poor are obliged to remain at home on account of lack of accommodation in our institutions, it is of the utmost importance that they should be visited repeatedly at their homes until the family become thoroughly familiar with the hygiene and prophylaxis of the disease.

And now again I must say a parting word on medication: Judicious medication can do so much good, and routine, injudicious medication, so much harm. No medicine, be it cod liver oil

or creosote, or any other supposed specific, is to be encouraged for a minute if it impairs the appetite or digestion of food. The patients who come to us consultants suppose we know the treatment to which we commit them when we send them away from home, and I think perhaps we have been too careless in not knowing more about it than we often do. I was much impressed by what was once told me by a distinguished alienist, — that he never sent a patient to an institution that he did not visit him regularly. In this case he felt a continued responsibility for his patient's restraint, which would differ from the responsibility in our case, of course, but we should have a pretty good general idea, not only of the locality to which our patient goes, but of the treatment to which he is to be subjected.

THE INTERRELATION OF MEDICINE AND SURGERY IN THE TREATMENT OF GASTRIC ULCER.*

BY HUGH CABOT, M.D., BOSTON,

Surgeon to Out-Patients, Massachusetts General Hospital, Visiting Surgeon to Baptist Hospital.

GEORGE G. C. BADGER, A.M., M.D., BOSTON,

Physician to Out-Patients, Massachusetts General Hospital, Visiting Physician to Baptist Hospital.

BUT a comparatively short time ago gastric ulcer, both in its acute aspects and in its chronic complications, was regarded as a purely medical disease, and ten years ago, to advise operation for chronic ulcer would have been to assume a grave surgical responsibility. The now famous statistics of Joslin and Greenough, however, called attention to the fact that the medical treatment of gastric ulcer was far from satisfactory. They showed that while the immediate mortality under medical treatment was not large, yet the ultimate mortality from the disease was very much higher than had been supposed, and that medical treatment could not be expected to permanently cure a very large percentage of the cases. These observations served to draw attention to the very notable work of Mr. Mayo Robson and his colleague, Moynihan, and to the extensive statistics of Mikulicz. From these it appeared that the mortality of surgical operation for this condition was less than the mortality under medical treatment, if the ultimate result in both cases was taken into account. The general feeling, especially in this community, was that the risk of operation was unwarrantable, and the profession was little prepared to offer for surgical treatment any cases except those which were obvious failures under medical treatment and which were too advanced to yield good results in the hands of the surgeon. Within the last two or three years, however, much attention has been paid to the surgical aspects of this question, and many cases have recently been operated upon with excellent results. It seems that the medical conservatism of the past has been extreme, and one is tempted to hope that the surgical activity of the future may be kept within reasonable bounds.

At the outset it may be admitted that the acute and subacute varieties of dyspepsia and acute gastritis are distinct medical conditions, and surgery is little likely to invade this domain. On the other hand, perforating ulcer of the stomach is, and long has been, a distinct surgical condition and one in which cure can only result from surgery.

ACUTE BLEEDING ULCER.

Acute attacks of hemorrhage from the stomach due to gastric ulcer are in the vast majority of cases to be treated medically. Under rest, morphia and nutrient enemata the hemorrhage can, as a rule, be controlled, and the tendency to recur within a short interval is in most cases slight. On the other hand, cases are sometimes seen in which, in the hands of the very elect, control of the hemorrhage by medical means cannot be obtained, and the patient will inevitably be lost unless surgical aid be sought. In a patient reduced by severe acute or long-continued moderate bleeding the conditions are most unfavorable for operation. With a low hemoglobin, as, for instance, in the vicinity of 50%, these patients show a very poor resistance to shock and are much more readily infected than under normal conditions. The mortality from operations upon the stomach is largely due to these two causes, and the mortality will increase immensely with the lowering of the patient's vitality. If, then, operation is to be advised it must be done at the earliest possible moment, when it can be shown that medical treatment has failed or is likely to fail. The indications for surgical intervention may be formulated as follows: Operation is to be advised,

(1) After failure of good medical treatment to promptly stop acute hemorrhage.

(2) If, though the acute hemorrhage has been controlled, slight but frequently recurring hemorrhage persists.

(3) If after the control of a large acute hemorrhage a second hemorrhage occurs within a short time.

All these three indications are based upon one general proposition: That in acute bleeding ulcer the failure of medical treatment must be early anticipated and that it is not wise to wait until the patient is so far reduced as to render the risk of surgical operation very great. The following case illustrates the point we wish to emphasize:

Mrs. D., patient of Dr. A. N. Broughton, to whom we are indebted for the history of the previous condition. Patient had a history of three attacks of hemorrhage during the past three years. On Jan. 2, 1901, there was a profuse hemorrhage of about a pint of bright blood. On Jan. 3, she collapsed without obvious cause and required vigorous stimulation with salt solution and strychnia, in order to tide her over this emergency. For the next week she gained steadily on nutrient enemata and was without hemor-

*Read before the Norfolk District Medical Society, Feb., 1904.

rhage. At this time she was seen by an able surgeon, who advised against operation. Patient's condition was at that time not thoroughly good. She was much blanched, though less so than a week previously. Pulse was good, temperature was normal. On Jan. 21, nineteen days after the first hemorrhage, mouth feeding, milk and lime water, half a dram each, was begun, and following this within a few hours a severe hemorrhage occurred. The question of operation was again considered, and she was seen by another surgeon who considered the condition too unfavorable for surgical intervention. The hemorrhage continued and the patient died three days later. Autopsy showed a duodenal ulcer lying directly beneath the abdominal wall in a very accessible position. There was much chronic thickening about the pylorus and the bleeding vessel was identified in the center of this mass.

This case is one which might have been saved by operation promptly undertaken. In deciding the question of hemorrhage it is not safe to rely upon blood vomited as an early indication. It must be remembered that a considerable proportion of so-called gastric ulcers are really duodenal, and a considerable amount of the blood may go into the intestine and not appear until some time after the bleeding has taken place. The two surest guides are the per cent of hemoglobin and the pulse. A sudden rise in the pulse rate or a tendency to continued, though slight, increase in rate must be regarded with suspicion, unless fully accounted for upon other grounds. If under medical treatment the hemorrhage once controlled does not recur, the clear indication is to wait, but we then come face to face with the question of whether we shall advise operation later, with a view to preventing the recurrence of hemorrhage. Recurrent hemorrhage is particularly characteristic of gastric ulcer, and while we are not in a position to postulate that hemorrhage having once occurred will recur, it is certainly true of a large number of cases. The situation is somewhat similar to that of chronic recurring appendicitis, a question upon which the medical community was long divided but upon which it is now largely in accord. We have come to regard a well-marked attack of appendicitis as so likely to be followed by another that operation in the interval is distinctly to be advised. This position has been achieved by pressure in two directions. First, it has been shown conclusively that the probability of recurrence is very great, and, second, the mortality of the interval operation is so low as hardly to be a serious consideration. But we cannot claim the same clearness in regard to gastric ulcer. Recurrence is not so common, and the mortality of the operation is, even in the most skillful hands, much greater than that for appendicitis. We are not, therefore, prepared to urge the treatment of gastric ulcer by surgical operation in the interval between hemorrhages, but there comes a point at which the tendency to recurrence is so marked and the probability of future immunity is so slight that operation will present the lesser evil of the two. The following case illustrates operation for recurrent hemorrhage:

Mr. C., thirty-three years old. At the age of fifteen began to have trouble with his stomach, frequently vomiting after meals. At this time he was a student, with irregular habits of eating. Attacks of vomiting occurred at irregular intervals, until April, 1901, when he vomited blood. In January, 1902, he vomited half a basin of bright blood and had tarry stools. At this time he was put upon nutrient enemata, which he says were continued for three months. In April, 1902, four months after his last attack, he again vomited half a basin of bright blood and for a time passed blood by rectum. During this time he had a good deal of fermentation and was washing his stomach with the tube with relief. He continued until June, 1903, when he again vomited blood in considerable quantity. During the five weeks previous to Oct. 23, 1903, he had much severe epigastric pain, especially after eating, relieved by vomiting. Examination showed a thin, but well-developed man; weight 91 pounds; best weight 135 pounds; pulse small and easily compressible. Examination negative except for the abdomen, which was moderately tender just below the xiphoid cartilage, and in the region of the stomach succussion could be obtained four hours after taking a glass of milk. Hemoglobin, 55%; skin dry and harsh, urine much diminished in amount, alkaline, without albumin or sugar. Examination with the tube showed much stasis, hyperacidity with hypersecretion. The stomach, in the morning, contained a considerable quantity of gastric juice with excessive hydrochloric acid, when nothing had been taken since the washing on the previous evening. The upper border of the stomach was in normal position, lower border one inch below the umbilicus. He was kept upon medical treatment, with nutrient enemata and careful feeding, with washing before supper and breakfast, for four weeks, when his hemoglobin had increased to 70%, his weight from 91 to 108 pounds. He was taking a moderate amount of food by mouth without distress. At this time he was operated upon. The pylorus was found to be adherent to the liver and thickened and indurated to the size of a pigeon's egg; the duodenum was sharply kinked and adherent to the stomach. Posterior gastro-enterostomy was done without difficulty. Four weeks later he was up and about, taking food freely without pain; the stomach contents were normal. Examination with the tube, six weeks after operation, showed the stomach normal in position and size. The contents left the stomach at about the normal time and was of entirely normal consistency. While it is too early to speak of the results as permanent, this seems to show one of the more brilliant possibilities of stomach surgery in carefully selected cases. Four months after operation he wrote that his weight was 135 pounds and that he was in excellent condition, without gastric symptoms.

The difficulty will come in deciding just what cases are suitable for an interval operation. We might formulate the indications somewhat as follows. We should operate:

(1) Upon cases in which the tendency to recurrent hemorrhage is well marked.

(2) Upon cases in which, though the recurrence of hemorrhage is not a prominent feature, yet the persistence of dyspeptic symptoms renders the patient unfit for an active life.

(3) Upon cases in which a long train of dyspeptic symptoms culminates in an attack of hemorrhage.

We should persist in medical treatment:

(1) In cases of acute hemorrhage not preceded by a train of dyspeptic symptoms and not showing marked tendency to recurrence.

(2) In cases in which acute hemorrhage is followed by apparent complete recovery, and in which the patient is free from serious annoyance from dyspeptic symptoms.

CHRONIC ULCER AND ITS SEQUELAE.

At the outset of any consideration of chronic ulcer we must disabuse our minds of the idea that hemorrhage is a constant symptom of gastric ulcer. The number of cases in which exploratory operations upon the stomach have been done is now so large that we are in a position to show definitely that in many cases hemorrhage either does not occur or is so trivial as to be entirely overlooked both by the patient and his physician. It can readily be demonstrated that chronic ulcer may exist for years without symptoms, or appear merely as a chronic dyspepsia, and that very extensive permanent damage may be done to the stomach and neighboring viscera. A considerable proportion of cases of hour-glass stomach are not preceded by hemorrhage; many cases of dilatation of the stomach due to pyloric obstruction are also free from hemorrhage; and yet in both these cases the permanent injury to the stomach is so great that the necessity for surgical operation is evident. We may divide the cases of chronic ulcer into more or less definite classes, according to the symptoms, and under these headings discuss their treatment.

(1) Cases of severe chronic dyspepsia without marked dilatation of the stomach. These cases have long been supposed to belong peculiarly to the physician, and certainly, in many cases, chronic dyspepsia is a medical disease and under proper treatment may be, if not cured, at least sufficiently palliated to make life tolerable. There are, however, cases in which, in spite of prolonged careful medical treatment, no considerable improvement is obtained, and these patients are practically invalided. More and more cases are accumulating in which these symptoms are proven to be due to chronic ulcer amenable to surgical treatment. They are obviously cases which will remain long in the hands of the medical men before the question of operation is considered, and it is entirely proper that they should so remain, but the point we wish to urge is that, if medical treatment fails to effect marked improvement of the symptoms, surgical advice should be sought and the question of operation carefully considered.

Miss T., thirty. History unimportant until 1899, when she began to have gastric pain after eating, with tenderness in the epigastrium and in the back over an area corresponding to the stomach. Vomiting frequent, never of blood. Diet consisted largely of bread and tea. Physical examination showed thin, pale woman, evidently in pain. Examination negative except for a very tender point just below the tip of the xiphoid cartilage; a corresponding point of tenderness in the back. Hemoglobin was 85%. She was at this time under medical treatment for three months, with much improvement in her general condition. Three years later, in August, 1903, she again came under treatment, having been practically an invalid during this time, unable to do any considerable amount of work without severe dyspeptic symptoms. Physical examination was practically as at previous visit. Because of persistent painful dyspepsia, due, probably, to ulcer, an exploratory operation was advised and eargely accepted. An attempt was made to wash the stomach, previous to operation. This resulted in very severe pain and collapse and therefore no data in regard to the size or position of the stomach could be obtained. Operation showed an hour-glass stomach, with a constriction about four inches from the pylorus, and the opening contracted to the size of a lead pencil. A double plastic operation like the pyloroplasty was done upon the anterior and posterior surfaces of the stomach. Convalescence was complicated by a sharp attack of pleurisy, but was otherwise uneventful. The patient is now eating a free diet such as she has not taken for years and is very comfortable. Three months later had gained thirteen pounds and was looking for work.

A certain number of such cases, at first apparently of chronic dyspepsia, will ultimately show the condition known as hour-glass stomach. This condition can be diagnosed only when well marked with distinct constriction forming two or more pouches. Robson and Moynihan have together and separately collected a very interesting series of these cases, in many of which the diagnosis was made before operation, but there must be a very large proportion of the cases which ultimately become hour-glass stomach which for many years are nothing but chronic dyspepsia and cannot properly be diagnosed as anything else. These must, under treatment, fail to show the improvement which might reasonably be expected, and should be operated upon before they have developed the extensive organic changes seen in true hour-glass stomachs. That in this attempt to relieve chronic dyspepsia which does not yield to medical treatment a certain number of errors will be made, must be generally admitted.

As illustration, a patient with mucous gastritis and colitis, operated upon for supposed gastric ulcer.

Mrs. G., twenty-eight. Seen in March, 1901. Three years before began to have pain in the abdomen, variable in position and character. One year ago persistent nausea and vomiting, retained very little food, pain in the epigastrium, worse after taking food. Vomitus is said to have been streaked with blood, but no great quantity of blood ever vomited. Urine scanty. At this time she began to take morphia for pain, in spite of which the vomiting continued. She had been in bed for the last six months. During the summer the urine was very scanty and was at times thought to be suppressed. Just previous to coming under our care she was operated upon for pelvic pain, with removal of the left ovary, but without relief of symptoms. When first seen she was much emaciated. Examination negative except for the abdomen, where visible peristalsis could be seen at almost any time, most marked in the region of the umbilicus. On the left side at

about the level of the umbilicus was a very sensitive area as large as the palm of the hand, without muscular resistance; no tumor could be felt. This tenderness extended into the left flank, where the left kidney could be felt. The examination of the stomach contents showed catarrhal gastritis. Inflation of the stomach showed the lower border three inches below the umbilicus, the upper border three inches below the ensiform — a somewhat dilated, markedly prolapsed stomach. As a positive diagnosis could not be made, exploratory operation was advised and accepted. The examination of the stomach at operation showed it to be normal. Upon opening the stomach the pylorus was found to be narrow but without organic disease. Examination was otherwise negative. A wide pyloroplasty was done for possible spasm of the pylorus. The immediate result was magical. Patient from having taken a half to three quarters of a grain of morphia a day was made perfectly comfortable and remained so for six months, when she again came under treatment, with symptoms quite similar to those before operation. The washing of the stomach showed an enormous increase in the amount of mucus, upon removal of which, with continued washing for a few days, the symptoms disappeared. About a week later she passed a most perfect mucous case of the large intestine, thus justifying the diagnosis of mucous gastritis and colitis. A more careful study of this case in the light of our present knowledge might have avoided an operation.

Unless more delicate methods of diagnosis are developed an absolute opinion will in many cases be impossible and a certain number of cases must be operated upon, upon presumptive evidence solely. Many practitioners will undoubtedly look with disfavor upon the possibility of operating upon cases in which, after the abdomen has been opened, no lesion can be demonstrated sufficient to justify surgical treatment. It must, however, be remembered that none of the great operations upon which we to-day rely as the main stay of surgical brilliancy have won their present position without a certain amount of unnecessary operating, and it is not probable that we shall arrive at knowledge sufficiently definite to enable us to operate only upon the proper cases without, in the preliminary stage, operating upon a certain number of improper ones. It does not seem, therefore, unduly radical to urge that physicians should be willing to advise investigation in cases of persistent chronic dyspepsia, with the full knowledge that occasional errors will occur, and an exploratory operation will be done without finding sufficient justification for further intervention. Without in any way underestimating the gravity of exploratory operations upon the stomach, we believe that it is well within the facts to state that the mortality from operations of this type should be but a small fraction of 1%, and that such a mortality need not weigh adversely against the extreme amount and long duration of the suffering which many of these chronic dyspeptics undergo. If we are to wait for absolute certainty of diagnosis before advising operation, we shall probably succeed in relieving but a small proportion of people who might have definite relief.

(2) Cases of chronic dyspepsia accompanied by dilatation of the stomach. In a certain proportion of cases of chronic dyspepsia examination by means of the stomach tube will show marked dilatation, and this is frequently regarded as of the atonic variety. It seems probable, in the present state of our knowledge, that the diagnosis of atonic dilatation has been considerably overdone and that many of these cases are due to obstruction at the pylorus of organic origin, due either to ulcerative processes in the pyloric region of the stomach or in the adjoining portion of the duodenum, or to perigastric adhesions originating either from ulcers of the stomach or duodenum, or to inflammatory conditions originating in the biliary passages. Experience in operations for the removal of gallstones shows a considerable number of cases of obstruction of the pylorus, and this is a condition which should always be considered in the attempt to diagnose a case of dilatation of the stomach. The main point at issue in this discussion is what we shall regard as sufficient evidence to prove the diagnosis of atonic dilatation and upon what indications we shall advise surgical investigation. That atonic dilatation is a very real condition is not for a moment to be disputed. It may result from a great variety of conditions tending to general debility, and it is probable that if the stomach tube were more used it would be found to exist more frequently than is now supposed to be the case. But if the dilatation be due to general and not to local causes, it must be demonstrable that the condition is relievable by medical treatment, and this relief must be permanent and not temporary. Thus, if dilatation, however great, can be cured or largely relieved by the proper use of the stomach tube and by general medical and hygienic treatment, the diagnosis of atonic dilatation seems justified. If, on the other hand, these measures fail to produce anything more than temporary relief, we must seek the cause elsewhere. It must be remembered that particularly in women with relaxed abdominal walls and a general tendency to ptosis of the abdominal viscera, sufficient sagging of the stomach may occur to produce more or less obstruction at the pylorus, provided always that the ptosis does not affect the liver and that the adhesions of the pylorus to the under surface of the liver are sufficient to keep it fixed in that relation. Under these circumstances we may have considerable dilatation of the stomach, together with a certain amount of hypertrophy, without any organic disease, and without, therefore, presenting any indication for operation. But under these circumstances proper medical treatment, coupled with an efficient abdominal binder, will generally give sufficient relief to enable us to exclude the presence of organic disease. On the other hand, in organic stricture the history will in many cases be important as tending to show previous acute inflammation either in the biliary passages or in the stomach itself. Such a suggestive history, coupled with present dilatation which

resists medical treatment, may be regarded as evidence of pyloric stenosis and justifies exploratory operation. This is illustrated by the following cases:

Mr. L., thirty. First seen in October, 1902. For five years has had dyspepsic symptoms consisting of pain (worse after meals), gas, but never nausea or vomiting. Constipation. Heavy feeling in the abdomen, with occasional heart-burn. Appetite is good; diets carefully on account of pain. This pain is in the epigastrium close to the tip of the xiphoid and a little to the right, where he says there has been tenderness. No blood ever seen.

Examination was negative except for slight tenderness in the epigastrium. After three months' medical treatment his condition was essentially the same. A diagnosis of gastric ulcer was made. On the 30th of December he came to the clinic writhing with pain, which had come on three or four hours previously without apparent cause. Examination of the abdomen showed the stomach to be much distended, with visible peristalsis and much tenderness. The stomach tube removed 1,500 cc. of partly digested food, with disappearance of the pain, distention and rigidity. One and one-half hours later the pain returned and 1,000 cc. were again removed with the tube. Chemical examination showed hyperacidity. When seen the next morning examination was totally negative and he was discharged in excellent condition. In spite of careful dieting he had, six days later, another similar attack, during which he is said to have vomited four quarts. The diagnosis of pyloric stenosis from ulcer was made, and operation was advised. A median incision was made and the pylorus was found high up, surrounded by a mass of adhesions and adherent to the lower surface of the liver. The whole pyloric region appeared to be a mass of scar tissue without evidence of malignancy. No attempt was made to dig the pylorus out of these adhesions. A posterior gastro-enterostomy was done, with complete relief. One year after operation he had increased fifteen pounds in weight, was in excellent health, eating freely of ordinary diet without pain. Inflation of the stomach showed it normal in size and position and all tenderness had disappeared. This case was one of complete, or nearly complete, pyloric stenosis due to an old contracting ulcer; and it is notable that, though the symptoms of ulcer dated back over five years, no blood was ever seen. There was no evidence of stenosis until Dec. 30, when it became suddenly complete.

Mr. H., thirty. First seen Dec. 15, 1902. For eighteen months had suffered from dyspepsia, gas, pyrosis, nausea and frequent vomiting. Vomitus bitter, often in large quantities and containing remnants of food eaten days before. Never vomited blood or passed any by rectum. Very costive. Examination at this time showed a much dilated stomach, marked stasis, and hyperacidity. Later he entered the Massachusetts General Hospital, and when discharged was advised to follow a carefully planned diet and to wash his stomach daily. A year later he again came under treatment being in miserable health in spite of careful and intelligent carrying out of instructions. He was much weaker and had lost a good deal of weight. He could work but two or three hours a day. The diagnosis of pyloric stenosis, probably due to ulcer, was made and operation advised, but refused. Three months later, in every way worse, he sought help, and eagerly accepted operation. At this time his weight was 108 pounds, his best having been 138.

Examination: Much emaciation and pallor. Hemoglobin 85%; pulse 82, of poor quality, otherwise negative save for abdomen. Epigastrium prominent, splashing easily obtained, no tumor or tenderness made out. Stomach capacity two and one-half quarts. Upper border normal, lower border two and one-half inches below navel. Hydrochloric acid excessive. Marked stasis. Urine normal, but scanty.

Under medical treatment he continued to lose ground, little if any food leaving the stomach.

March 13, 1904, operation showed much hypertrophied and dilated stomach. Contracted scar near the pylorus entirely occluded the opening. Posterior gastro-enterostomy. Uneventful recovery. May, 1904, is entirely free from symptoms. Weight, 128 pounds.

Mr. T., fifty-two, first seen in December, 1900, well illustrates the temporary character of medical relief. Has had "spells of indigestion" for forty years, which consist of pain in the stomach followed by a longing for food, often by nausea, occasionally by vomiting. Three years ago vomiting became more frequent, and at times amounted to from one to two quarts, often containing much old food. Has lost weight and strength. Two years ago, as the result of a vacation, was much improved, but on resuming work ran down hill again. Four months ago, gave up his work on account of ill health. Three days ago says he drank twenty glasses of water and a few hours later vomited two quarts. No blood at any time. Examination shows a much emaciated man, weak, hardly able to walk, with dry, rough skin; otherwise negative except for the abdomen, which is prominent, with marked fulness below the umbilicus, with visible peristalsis and splashing. Hemoglobin, 70%.

Examination with the tube showed that the stomach held nearly four quarts, with very much diminished hydrochloric acid, no lactic acid. Under medical treatment he improved very much. At this time a diagnosis of pyloric obstruction due to ulcer was made. Operation advised and refused. He was seen again about a year later, in much the same condition. During this interval he had carefully and intelligently followed the instructions given him regarding his diet and the use of the tube. He had kept at work and in fairly good health. The daily use of the tube was necessary, however, once, twice, or even three times, to prevent severe dyspeptic symptoms. In the following year he lost ground rapidly from starvation, developed pulmonary tuberculosis, and died. Autopsy showed an immense dilated stomach, with a healed ulcer at the pylorus causing almost complete stenosis.

This case was one particularly suited to operation and would in all probability have given as brilliant a result as the case above described. It is against the withholding of operations from cases of this class that we would particularly advise. The development of pulmonary tuberculosis is not uncommon in these neglected cases.

Before closing we wish to draw attention to the close relation which should exist between the physician and the surgeon in the treatment of these cases. Neither alone can do justice to his patient, and only when they work together and in thorough harmony can the best results be expected. All stomach cases are primarily in the province of the medical man, but it is coming to be believed that many of them ultimately become surgical, and if this is the case

the medical man who has more or less constant relations with a surgeon is likely to allow fewer cases to slip through his fingers and is more likely to be in a position to avail himself promptly of the possibilities of surgery. On the other hand, we are strongly of the opinion that few surgeons are in a position to deal with these cases alone; few are sufficiently skilled in medical diagnosis to come to sound conclusions with any degree of certainty, and they ought, for the best interests of their patients, to avail themselves of the services of a medical man both for diagnosis and treatment. In fact, the part the surgeon will play is comparatively small, and the treatment both before and after operation is in the vast majority of cases clearly medical. Thus, by the intelligent co-operation of both physician and surgeon the best results will be obtained in a large series of cases, and he who attempts to combine in his own person the functions of these two will be certain in the long run to obtain inferior results. We may sum up the indications for surgical treatment as follows:

(1) Perforating ulcers of the stomach.

(2) Bleeding ulcers in which the hemorrhage either cannot be controlled by medical means, or, having been controlled, tends to recur, thus placing the patient's life in immediate danger.

(3) Cases with a long history of dyspepsia culminating in hemorrhage, after the hemorrhage has been controlled by medical means and the patient put in proper condition for operation.

(4) Cases of intermittent recurring hemorrhage which, though individually small in amount, tend by their persistency to produce a profound anemia.

(5) Cases of chronic dyspepsia without dilatation, which fail to yield to proper medical treatment.

(6) Cases of chronic dilatation of the stomach which fail to yield to medical treatment and are not due to a general visceral ptosis.

SPINDLE-CELL SARCOMA OF FOOT. AMPUTATION. RECOVERY. LUNG METASTASES. DEATH. AUTOPSY.

BY CHARLES L. SCUDDER, M.D., BOSTON,
Surgeon to the Massachusetts General Hospital, Boston, Mass.

A. R. L. A medical student about twenty-two years old.

Apr. 30, 1903, he fell down stairs, twisting the right foot. He was unable to walk on account of the sprain, and has used crutches since that time. The foot and ankle have been treated by massage, active and passive motion, and for a short time by immobilization of the ankle. He complained in July, 1903, of a dull, throbbing pain in the foot. He has gained in weight recently, and has been feeling particularly well.

Examination. — The right foot is swollen on the dorsum and inner side of the sole; the dorsum is edematous. There is some tenderness along the first metatarsal bone. The superficial veins are somewhat enlarged and distinct in the sole of the foot. Movements of the ankle are about normal. Enlarged lymphatic glands are to be felt in the groin.

First operation July 29, 1903. An incision into the sole of the foot evacuated a large quantity — of two or three ounces — of apple-tapioca-pudding-like material, mixed with blood. The cavity containing this material occupied the whole sole of the foot. The calcaneo-scaphoid joint was bared. The bones appeared intact. The wound was partly closed by suture, and drained by a wick of gauze. The material removed at this operation was examined and a report made of sarcoma.

Laboratory No. 37-116. July 29, 1913. *Pathological Report upon Material Removed from Sole of Foot.* — Microscopical examination showed bundles of closely-packed spindle cells running in all directions. The nuclei were small and oval, and the cytoplasm not well marked. There were many small and very thin-walled vessels.

Spindle-cell sarcoma.

(Signed) CHANNING C. SIMMONS, M.D.

Second operation, Aug. 5; the glands in the groin were removed. The pathological report stated that these glands were not malignant.

Third operation Aug. 8; the leg was amputated eight inches below the tuberosity of the tibia.

Laboratory No. 38-43. Aug. 7, 1903. *Report from Examination of Amputated Foot.* — Microscopical examination of the tissue from the internal malleolus showed in places closely packed bundles of spindle-shaped cells with oval nuclei. These cells merged in some parts of the section into loose myxomatous tissue, largely necrotic. In other places the cells were nearly round in shape. The growth was intimately connected with the tendons and muscles, and was surrounded by inflammatory connective tissue. Examination of the nodules at the base and head of the metatarsal bones showed the same type of cells in varying proportion, but largely necrotic. The periosteum was normal. The growth apparently originated from the muscles and tendons.

Diagnosis: Spindle-cell sarcoma.

(Signed) CHANNING SIMMONS, M. D.

The boy recovered well, the stump healed satisfactorily, and he went back to the Medical School, and in the fall was planning to get an artificial leg. He caught cold during November, 1903, and had a severe cough which required the services of a physician. He entered the hospital Dec. 26 with evidences of an intrathoracic lesion. He died Dec. 30, 1903.

An autopsy was had and it was found that he died from sarcomatous metastases in the lungs.

Partial report of final autopsy by Dr. Jones of Lowell, Mass. — Left lung greatly enlarged, extending beyond the median line, crowding the right lung, pushing the heart forward to the median line, and pushing the diaphragm markedly downward.

The tissue of the lung had lost any distinctive appearance, and was replaced by soft white masses the size of a hazel nut, surrounded by a softer semi-gelatinous substance.

Distributed through these areas were dark-colored clots of blood the size of an ordinary white bean, slightly larger.

The left pleura was adherent to the parietes and the diaphragm by firm adhesions.

The right lung was much less diseased, but contained masses similar to those in the left lung. The tissues were much firmer in texture than those of the left side.

Report from the pathological laboratory upon a specimen of lung tissue forwarded from the autopsy. — A microscopical section of the lung was furnished by Dr. Jones and showed spindle-cell sarcoma.

(Signed) DR. J. H. WRIGHT.

This case of spindle-cell sarcoma, originating in the soft parts of the sole of the foot, is extremely interesting, because it has been possible to follow the disease from its apparent beginning until death. It was the appearance of this patient at my clinic at the Massachusetts General Hospital last year which suggested the study of the relative malignancy of the sarcomata of the long bones.[1] At the time that the boy was admitted to the service, it was thought that the disease originated in the bones of the metatarsus. Subsequent examination has proved that the origin of the disease was in the soft parts next the bone. The very great malignancy of this spindle-cell sarcoma is evident. From the initial sign of the spraining of the foot to the time of the boy's death, there were only eight months. The question arose in connection with this case: At what point is it best to amputate? Amputation was done at about eight inches below the tubercle of the tibia. It was thought that if metastases had already taken place, a higher amputation would be of no advantage, and certainly if metastases had not taken place, a higher amputation would probably not have availed against metastases. I believe that exploratory incision into malignant growths, whether sarcoma or cancer, is unwise. There are cases recorded in which it would seem that the exploratory incision was the occasion of subsequent metastases. In this particular instance the question may very properly be raised: Did the incision into the sole of the foot, with subsequent curetting and laceration of veins, contribute in any way to the metastases? Certainly, a very thorough examination of the body of any individual with sarcoma of the extremities should be made, to determine, if possible, the existence of metastases before any radical operation is attempted.

Clinical Department.

BOSTON CITY HOSPITAL CLINICAL MEETING.

APRIL, 1904.

DR. F. B. MALLORY in the chair. DR. L. R. G. CRANDON, secretary.

There were sixty in attendance, and cases and reports were presented as follows:

I. STRANGULATED FEMORAL HERNIA, RELIEVED BY ABDOMINAL OPERATION. II. REYNAUD'S DISEASE; GANGRENE OF FOREARM.

BY J. B. BLAKE, M.D.

CASE I. N. H., female, thirty-five, married, entered Boston City Hospital Mar. 14, 1904.

Family history, negative. In Boston City Hospital several years ago for same trouble. No operation. Seven children; no miscarriages.

Two days ago, severe pain in abdomen. Vomiting and abdominal tenderness to marked degree. Bowels constipated. No jaundice. General examination negative. Locally a small mass in left groin below Poupart's ligament; freely movable, not painful, no impulse; marked tenderness and spasm in left lower abdomen.

Mar. 14, 1904, operation, Dr. Blake.

Abdominal incision, four inches long, in median line below umbilicus. Intestines dilated and reddened. Fluid in peritoneal cavity. Knuckle of gut caught in femoral canal. General traction failed to relieve this, so ordinary operation for strangulated femoral hernia was done. On opening sac, considerable fluid escaped. About three inches of dark purplish gut found. No omentum. Stricture of gut removed by incision up towards abdomen. Color and peristalsis returned under hot salt solution, and gut was returned to abdomen, resection being unnecessary. Owing to patient's condition radical operation for cure of hernia not attempted. Skin closed with silkworm gut. Small wick through femoral canal. Abdominal incision closed with silkworm gut. One wick down in pelvis, brought out at lower end of wound. Corrosive dressing. Bandage and swathe. Shock, enema.

Mar. 18. Patient made only fair recovery from ether. Moderate shock. Temperature normal. Now fairly comfortable. Bowels move well with enemata and calomel. Wicks removed and replaced to-day. Comparatively slight discharge. Mar. 22. Temperature normal. Full diet. Mar. 26. Some redness about femoral wound now going. Sinuses closing. Temperature normal. Bowels move well. Apr. 14. General condition has steadily improved. Patient up and about. Apr. 22. Wounds practically healed. Swathe. Discharged relieved.

Pathological report: No organism in smear from peritoneal fluid.

Urine: High; acid; 1,026. Mar. 14, 1904. Albumin, $\frac{1}{8}$%; sugar and bile, 0; sediment. Few free blood corpuscles; few hyaline and finely granular casts. Occasional leucocyte; few epithelial cells.

CASE II. I. B., female, thirty-eight years old, entered hospital on Apr. 10, 1904.

Family history, negative. Rheumatism ten years ago. Typhoid pneumonia two years ago. For past twenty-seven years fingers have been numb and white at times.

Six days ago, slight injury to hand while working. Hand painful next day. Three days ago fingers became discolored and black. Line of discoloration has gradually moved up arm. Very painful and tender. Unable to sleep for past three nights. Three days ago struck left hip against door and now has blackened tender area over site of injury.

Well developed and nourished. Tongue dry and coated. No glands felt. Heart and lungs negative. Abdomen negative; knee jerks normal. Gangrene of right thumb and first three fingers extending two thirds way to elbow. Veins injected.

Apr. 18. Requires morphine for pain. Line of demarcation forming about middle of forearm. Fingers dry and parchment-like. Blood culture shows moderate number of streptococci in blood. Apr. 27. Operation. Amputation. Dr. Blake. Esmark. Ether. Amputation one and one-half inches above demarcation line. Muscles grayish in places and not healthy looking. Very little bleeding. Skin sutured with silkworm gut. Rubber dam wick each end incision. May 1. Dressed twice since operation. Some bloody serum pressed out of stump. Clean. Temperature slightly elevated after operation. Dropped to normal after first dressing. May 5. Temperature normal. Comfortable. Dressed daily. *Urine:* Negative throughout.

Pathological report: Arterio-sclerosis. Clinical diagnosis, Reynaud's disease.

[1] See "A Study of Certain Cases of Sarcoma of the Long Bones from the Massachusetts General Hospital Clinic." BOSTON MEDICAL AND SURGICAL JOURNAL, June 2, 1904.

I. LARYNGOTOMY AND REMOVAL OF ONE CORD FOR BENIGN TUMOR OF LARYNX. II. OPERATION FOR "DROPPED KNUCKLE."

BY F. J. COTTON, M.D.

CASE I. The patient, a man of sixty, first showed dyspnea a fortnight before entrance to the hospital. He was sent in from the throat department as a case of either malignant or specific disease, having an immobile right cord and thickening about the posterior part of the cord without ulceration. Potassium iodide was tried but the dyspnea increased, coming on in night paroxysms so alarming that a preliminary tracheotomy was done on Mar. 2. For a day or two there was some inhalation of liquids and a consequent severe bronchitis. After waiting for this to subside, a median laryngotomy was done under ether with a sponge wrapped tracheal camula with the necessary later aid of adrenalin and cocain in the larynx. The pathologist's immediate report of the tissues removed was non-malignant, and the operation of partial laryngectomy which was expected was given up; the soft tissues of the whole right inner side were cut and gorged out and the larynx lightly packed. Except for a fleeting phlegmon of the neck on the second and third day recovery was uneventful. The tube was finally removed at eight days.

The patient now has a practically closed wound. He breathes normally and has a very tolerable though of course hoarse voice, which seems to be still improving. There is still some difficulty in swallowing semi-solids; solids and liquids cause no trouble.

CASE II. Man of forty-four; fractured the metacarpal bone of the first finger just behind its head, in a fall. He was treated as an out-patient, but after three weeks showed an unsatisfactory result. There was a marked "dropped knuckle" and an inability to flex the knuckle for more than a third the normal range — the limitation being apparently fibrous. An x-ray taken showed considerable displacement of the distal fragment up and forward toward the palm. Dr. Lothrop sent him in for operation, and on Mar. 31, under ether, an incision was made on the radial side of the metacarpal and an open osteotomy of the bone was performed, approximately along the line of fracture. The distal fragment was pried into place with a little trimming of bone and the finger put up in flexion. The wound was closed tight. The hand now shows no dropped knuckle at all. There is some excess of bone (callus?) at the site of fracture. Full flexion is possible; as to extension it is impossible to say as yet it should be good. The case is shown as an example of a class of cases that should be operated often; they seem trivial, but if good results are not obtained by ordinary treatment of these fractures, the disability is serious. They call for the best efforts we can give.

TABES DORSALIS, WITH SURGICAL COMPLICATIONS.

BY ABNER POST, M.D.

The patient entered the hospital with retention of urine. A catheter was easily passed and was tied in. It was said, by the patient, to occasion very severe pain which kept him awake and caused him to scream out. A careful examination showed that there was no mechanical difficulty with the water passage and disclosed the presence of a tabes which was evidenced by a loss of knee-jerks and by fixity of the pupils. During this examination attention was attracted to a long scar on the right side of the abdomen which the patient explained was made about two years before. He gave the following history: Between two and three years previous he had had abdominal symptoms, of which pain was the most marked, which raised a suspicion of gastric ulcer. That suspicion was later set aside and he was suspected of an appendicitis. The symptoms were somewhat indefinite, but so severe as to call for an exploratory operation. The appendix was found to be normal but was removed and the incision was extended so as to allow of the examination of the gall bladder and its vicinity. This further examination disclosed nothing abnormal. Paroxysmal pains had continued during these two years and persisted after his admission to the hospital. These pains were evidently the so-called crises of tabes and at the present time they occur with considerable frequency during the night and cause the patient to cry out so violently as to compel his isolation. An additional symptom in this case is the marked difficulty in emptying the rectum.

The patient was seen a little later by Dr. J. W. Courtney who confirmed the diagnosis of tabes and discovered in addition certain difficulties of speech which raised the suspicion of beginning general paralysis.

INTESTINAL OBSTRUCTION FROM STRICTURE DUE TO ADENO-CARCINOMA, RESECTION OF COLON, RECOVERY. IV. PHLEBITIS OF THE VENA CAVA FOLLOWING TYPHOID. V. SUPPOSED TUBERCULOUS TUMOR OF THE PONS CEREBRI. VI. SENILE GANGRENE OF THE LEG, AMPUTATION OF THIGH, RECOVERY. VII. REYNAUD'S DISEASE.

BY H. W. CUSHING, M.D.

CASE I. The patient, a boy of nine, was convalescent from an extremely severe attack of appendicitis in which the onset was sudden. Gangrene, perforation and general peritonitis followed in four days. On the sixth day of the attack he was admitted to the hospital in a marked condition of toxemia. Immediate operation by Dr. Cushing. The intestine was found more or less adherent, with collections of pus between the loops throughout the abdomen and in the pelvis. The distal half of the appendix was gangrenous. The appendix was removed, the abdomen irrigated with salt solution and drained in the appendix region, the flanks, and the pelvis with gauze wicks. The patient left the operation table in a bad condition and for twelve days was very dangerously ill. For the first five days of this period a fatal result was constantly threatened. There was the "peritoneal" expression of the face, slight cyanosis, dark colored vomitus and more or less delirium for twelve days. On the eleventh day the temperature was 103° F., pulse 115, and there was a friction rub in the left lower chest. After the twelfth day the patient began to improve and gradually recovered. The drainage was gradually discontinued and the wound is now (eight weeks after operation) nearly healed. The boy is practically well.

The points in this case which attract attention are the following:

(1) The severe type of the disease, general suppurative peritonitis due to a mixed infection of streptococcus pyogenes, staphylococcus aureus, colon bacillus and another micro-organism not specified.

(2) The treatment: In this, the following things seem to have influenced the result;

The thorough irrigation of the abdomen with hot salt solution; thirty-three to thirty-six pints were used. Every pocket of pus which could be found among the adherent loops of intestine was gently opened during the irrigation, some

being found even in the splenic region, and the washing was continued till the return current from the external wound flowed out clear.

The gauze drainage was extensive. Next, the post-operative effect of subcutaneous infusion of adrenalin and salt solution. During the first few days following the operation when the patient's condition was so critical, the injections would be followed in one half to three quarters of an hour by a marked change. The skin would lose its cyanotic tinge and become flushed. The surface from cool and moist would become warm. The facial expression change from that of a patient "*in extremis*." The respiration became fuller and stronger. The pulse regular, stronger in volume and slower in rate. The injections[1] were repeated every twelve hours for twelve days and seem to have had an important influence on the recovery of the patient.

The theory on which it was used was that the action of the heart would be improved, that the toxins in the blood would be diluted and that the resulting diuresis would more rapidly excrete the products of the infection toxemia. The actual observation of the patient and a study of his "graphic" record seems to corroborate this idea.

CASE II. This case illustrates the effects of adrenalin infusion in repeated doses. This patient, a boy nine years old, was also a case of general suppurative peritonitis due to a perforation appendicitis with fecal concretion and gangrene. This case was not so acute as the one just described and the patient was not so dangerously ill for so long a period; and the peritoneal cavity was not so generally infected, but at one time his approach to a moribund condition was closer. The appendix was removed by Dr. George H. Monks. The abdomen was drained in the appendix region, the pelvis and the flanks by gauze strips through a median and a right iliac, oblique incision. The culture from the abdomen showed streptococcus pyogenes and colon bacillus. On the second day after the operation the patient almost died. The temperature fell to 95.5° F. Pulse was scarcely perceptible, intermittent and rapid. The face, especially the nose, the ears and finger tips were cyanotic. The pupils dilated. The respiration was shallow, the skin cool and moist. There was marked muscular relaxation and the appearance, the listlessness, of extreme exhaustion.

The patient at this time received 200 to 250 cc. of adrenalin and salt solution in the same manner and of the same strength as has been previously described. The effects were noted in one-half to three-quarter hour later. The respiration improved, the cyanotis disappeared, the skin regained its normal color, then became somewhat flushed. The pulse which at times could not be felt at the wrist began to increase in strength and volume and to become slower in rate. The temperature rose to 98. The patient then gradually reacted, was severely sick for a number of days and eventually recovered. The injections were repeated once and twice daily for seven days. The wound healing was delayed by a fecal fistula which closed spontaneously in twenty-three days.

In both these cases which were cases of marked infection the low leucocytosis at the time of operation attracts attention; 8,800 in the first and 7,400 in the second. This increased after operation to 17,000–18,000 in the first and 13,350 in the second. This record seems to correspond with the present idea of the relation of leucocytosis to acute infection. The graphic record is appended.

[1] The injection consisted of slowly injecting by gravity 200 to 250 cc. of the adrenalin and salt solution into the subcutaneous tissue of the front of the chest. The temperature of the solution was about 105° F. It took to inject this amount from 15 to 20 minutes. It was repeated every 12 hours. The solution was, R Adrenalin Chloride Sol. (Parke, Davis & Co. Adrenalin 1 pt. Normal Salt Sol. 1,000 parts c Chloretone 5%.) 10. cc. Salt Solution (BCH. R = Sodium Chloride [Na Cl] 9.0%. Calcium Chloride [Ca Cl$_2$] 0.30. Potassium Chloride [KCl] 0.10. Distilled Water [1,000.00 cc.]) 500 cc. This makes a 1 to 50,000 Solution of Adrenalin.

The history of the case was as follows:

CASE III. This case was a man forty-eight years of age in whom the colon had been resected at its junction with the sigmoid flexure for intestinal obstruction due to cancer.

The history of the case was as follows: The patient was well till fifteen years ago. He then had an attack similar to the present one, but less severe. For ten to twelve years past there has been habitual constipation requiring the more or less constant use of cathartics.

Feb. 10, 1904. Severe intermittent cramp-like pains in the abdomen and vomiting occurred. For three days there was no dejection. The vomiting continued. The abdominal pain almost disappeared. Feb. 15. The patient entered the Boston City Hospital still vomiting. The ascending colon was apparently quite distended throughout its entire length forming a cylindrical tumor about four inches in diameter and extending from the liver to the iliac region. With the exception of a large scrotal hydrocele the physical examination was otherwise negative.

For a few days the patient under treatment was more comfortable. Then on Feb. 20, the vomiting became more frequent and fecal in character. The abdomen became distended and quite tympanitic. Ether was given and the abdomen explored to find and relieve the cause of the obstruction. A six-inch incision was made in the linea alba extending from the navel to the pubes. The small intestine, much distended, at once prolapsed through this opening. Exploration of the abdomen was so impeded by these distended prolapsed loops of intestine that an attempt was made to empty them. The gut was incised in two places and about 500 cc. of liquid feces evacuated. These intestinal incisions were then sutured. It was then possible to explore the abdomen, but not easily. It was still filled with distended intestine. Nothing was found except the distended ascending colon which was fully four inches in diameter. On account of the patient's condition becoming alarming and also the failure to find any cause of obstruction, an incision was made through the abdominal wall obliquely over the cecum. The cecum was sutured to the wound and opened. Two litres or more of liquid "pea-soup-like" feces were drained off. A rubber tube was now fastened into the colon wound by two superimposed "purse-string" sutures. As further exploration seemed likely to kill the patient the median incision was closed by "through and through" silkworm gut sutures and the operation ended.

There was marked shock, but the patient recovered from the ether and gradually reacted under treatment. The intestine gradually emptied itself through the tube in the colon into a bottle at the bedside and the obstruction was temporarily relieved.

Feb. 24. The tube was removed. The vomiting and pain had ceased. Mar. 7. The patient had regained strength and was in good general condition. The fecal fistula was still open. The median wound had healed. It was then noticed that unless the intestine was emptied by laxatives and enemata the symptoms of intestinal obstruction again recurred. It was therefore determined to operate again and to make an attempt to locate and relieve the obstruction which was now supposed to be a neoplasm situated in the wall of the intestine and filling its lumen. On account of the distention of the colon ending at the hepatic flexion the obstruction was thought to be probably located at this point, and on Apr. 13, after careful feeding and preparation, a second operation was done.

Under ether the abdomen was incised in the median line above the umbilicus and explored. Careful examination of the transverse colon and vicinity failed to find anything abnormal. Finally, after exploring the whole abdomen carefully without result, suddenly a small, hard, movable mass was by chance felt with difficulty in the left iliac region. An oblique incision four inches long was now made in the left lower quadrant of the abdomen and through this wound the mass was with difficulty protruded.

It proved to be a tight, narrow, annular stricture of the intestine at the juncture of the descending colon with the sigmoid flexure. With considerable difficulty the growth was isolated by clamps and two inches of the intestine with its adjacent mesentery resected. No glands were found. The intestine was then closed by an "end to end" union. This was done by a "right angle," continuous, fine silk suture reinforced at one or two points by interrupted "Lembert" sutures. The abdominal wounds were sutured without drainage. The difficulty of the operation was much increased by the slight mobility of the growth and by a very thick, fat mesentery or meso-colon.

The operation lasted one and one-half hours. There was considerable shock. Examination of the tumor by the Pathological Department of the hospital showed the resected mass to be an adeno-carcinoma which had so occluded the lumen of the intestine as to leave only an opening 2 to 3 mm. in diameter.

After the first day following the operation the patient's condition steadily improved, and on the fifth the temperature and pulse reached normal and remained so. The highest temperature, 101.8, was on the night following the operation. The highest pulse rate, 120, was on the evening of the next day after the operation. The wounds healed by first intention.

There was a spontaneous, normal dejection on the seventh day after the operation. The artificial anus closed spontaneously on the eleventh day after the intestine was resected and the obstruction re-

moved. The fecal discharge from it ceased much earlier. The patient at the time of discharge from the hospital was apparently well.

The points in the case to which especial attention is directed are as follows:

(1) The importance of operating in such a case in two "sittings." If an attempt had been made to find and resect the intestine at the first operation the patient would have died of shock. The artificial anus relieved the obstruction, emptied the intestine; the patient had an opportunity to regain his strength and the second exploration was made with an empty intestine instead of with a semi-paralyzed one full of stagnant feces and ptomains.

(2) The multiple wounds of the abdomen. The two wounds in the median line overlap so that the resulting scar extends almost from the sternum to the pubes. Then there is the four-inch oblique incision in the left iliac region through which the colon was resected and the three-inch oblique one in the right iliac region which served for the temporary artificial anus. These at present are firmly healed and show no tendency to herniæ.

(3) The difficulty of making an extended exploration of the abdomen through a median incision, and also resecting an intestine through an incision in the left iliac region with a discharging fecal fistula in close proximity to these wounds without infecting the peritoneum.

(4) The rapidity with which the artificial anus healed as soon as the necessity for its presence ceased.

The resected portion of the colon containing the adeno-carcinoma was shown and also a microscopic section of the neoplasm, which was prepared by the Pathological Department under the direction of Dr. F. B. Mallory. The specimen showed the extreme narrowing of the intestinal lumen by the growth. The histological examination showed that the resection of the intestine had been made well beyond the limits of the disease.

CASE IV. A patient, a man forty-three years of age, a clerk by occupation, who was admitted to my service for a periphlebitis and varicose eczema of the left leg, with superficial ulcer. This condition was relieved by the usual treatment in two to three weeks. On examination a marked varicose condition of the veins of both lower extremities was found, and also an extreme dilatation of the superficial veins of the abdomen, especially in the lower half. The patient stated that this condition had been present for nine years, and that the distention of the superficial veins was first noticed near the groin. That it had appeared here before the varices of the legs were noticed. A thorough physical examination failed to show any cause for such extensive venous obstruction. The examination of the chest and abdomen was negative and no cause for this extensive superficial venous dilatation was suggested till attention was called to an attack of typhoid fever thirteen years previous, which was complicated by a phlebitis of the lower portion of the vena cava causing obstruction to the venous circulation below that point, and the subsequent development of the collateral superficial venous circulation of the abdomen and the dilated veins of both lower extremities. Dr. George G. Sears, who first called attention to this diagnosis, commented on its great rarity, and showed a patient from his service convalescent from typhoid, who apparently illustrated this condition of abdominal phlebitis in an acute stage. The diagnosis could not be so definitely made in this case as in my patient, in that the cord-like vein was not actually felt and the patient was not ill so long; but it is difficult to explain the clinical picture presented by any other hypothesis.

CASE V. The patient, a girl, nineteen years old, presented the following history: When a child she fell, striking her head in the frontal region. Her history is otherwise negative till two years ago, when her present illness began.

The first symptom noted was intermittent headache which has persisted. Next appeared vomiting. First, eighteen months ago, now a marked symptom. One year ago trouble with vision caused her to visit the Massachusetts Eye and Ear Infirmary and for the past nine months she has worn glasses. Five months ago appeared difficulty in writing, in articulation, facial paralysis, and loss of vision of the left eye; one month ago she discontinued her occupation and the vision of the right eye was lost. Two weeks ago inco-ordination of the right eye was noted. Since then she has slowly grown worse. The urine shows nothing abnormal. The temperature and pulse are not especially affected. There is no loss of memory or intelligence. There is ptosis of the right eyelid. The left eye cannot be closed; the pupils in both are dilated and do not react to light or distance. Dr. Greenwood reports that the discs are affected in both eyes, are elevated, the left checked, the right showing beginning atrophy. There is deafness in the left ear. The left facial nerve is paralyzed. The tongue protrudes to the right. The patient talks slowly and articulation is difficult. The patella reflexes are normal. There is no ankle klonus, no Babinski or Kernig reaction. Some inco-ordination of the upper and lower extremities is present. The patient walks slowly and carefully. She staggers slightly. Examination of sensation of the trunk and extremities shows nothing abnormal. Vomiting at irregular intervals, vertigo and frontal headache are the present chief symptoms.

CASE VI. A case in which gangrene involving the foot and leg nearly to the knee had occurred.

The patient was a woman, age seventy-eight, who in January, 1904, noticed pain in the left foot. The foot soon became red and swollen. In two weeks the great toe became gangrenous. There was no history of trauma. The process of dry gangrene slowly extended until it reached nearly to the knee. Dr. Cushing amputated the limb at the junction of the middle and lower third of the thigh. The femoral artery at the point of section was very rigid and almost occluded. It was again resected one and one-half inches above the first point of division. The patient bore the operation well. There was very little shock following it. The stump healed by "first intention" without drainage under one dressing.

The dissected amputated limb was shown. The popliteal artery was occluded by a clot throughout its entire length. In its proximal portion the wall was so calcareous that it could scarcely be cut with a scalpel. The gangrenous area involved the foot and leg nearly to the knee. The black color of the surface was marked and the characteristic appearances of "dry" gangrene were well shown.

CASE VII. In connection with the case of senile gangrene of the leg a case was shown in which gangrene of the fingers resulting from Reynaud's disease had occurred. The third finger of the right hand was first affected, then the fifth and finally the fourth. This patient was a man, thirty-two years old, a Russian

Jew and a tailor by trade. There was no history of traumatism. There was marked pain, spasmodic, referred to the fingers. There was no pulsation in the radial artery at the wrist. The fingers were amputated. The arteries were found occluded by a thrombus. The pain, which had caused a great deal of discomfort to the patient, disappeared after the removal of the fingers. No cause for the radial obstruction has been discovered.

Another fact of interest is that the amputation wounds have healed. The phenomena of local asphyxia or syncope have not been noted in this case.

(To be continued.)

Medical Progress.

REPORT ON OBSTETRICS.

BY FRANK A. HIGGINS, M.D., BOSTON.

(Concluded from No. 9, p. 246.)

PREVENTION OF VISCERAL PROLAPSE AFTER PARTURITION.

GALLANT[13] believes that women should not, on getting up after the puerperium, suffer from muscular weakness, abdominal distention and ptosis, or uterine displacement and lacerated parts. To prevent displacement, he insists that his patients shall not be allowed to lie on the back, but must be kept on the side; he tampons the uterus for two or three weeks after the fundus is below the brim, and finally he fits a pessary to be worn from three to six months. For muscular weakness, he advises massage with passive and active exercises begun within a few days after labor, and in addition the patient is gotten out of bed as soon as possible, usually on the ninth day. For abdominal distention and ptosis, in addition to the above, he advocates a snug binder while in bed, and when the patient gets up, a specially fitted corset is worn, which is always applied while the patient is recumbent, and with the hips elevated.

COAGULATION OF BLOOD IN ECLAMPSIA.

Douglass[14] examined the blood of twenty-two eclamptic patients, and from his observations there is little difference in the coagulation time of healthy pregnant and puerperal women, and of eclampsia before and after delivery, and that there is nothing, as far as a study of the coagulability of the blood goes, to support the contention that the thrombi found in certain organs in fatal cases of eclampsia are due to an increased coagulability.

TREATMENT OF SEVERE POSTPARTUM HEMORRHAGE.

Fritsch[15] describes a method which he has used successfully for thirty years. In cases where the hemorrhage is due to atony of the uterus after expression of the placenta, he inserts his hand between the recti muscles, and grasping the uterus, he presses it forwards with both hands into a position of anteflexion over the symphysis. He then packs the space behind with cloths and towels, holding them tight with a roller bandage or binder around the abdomen, allowing it to remain in place for twelve hours. The body of the uterus rests on and above the symphysis, and its bleeding walls are pressed so firmly together that there is no opportunity for further hemorrhage. All the manipulations are extravaginal, and therefore require no preliminary disinfection. When the hemorrhage is due to lacerations, his method is to close the labia with one hand and push the vulva vigorously upward, exerting counter-pressure with the other hand on the fundus for half an hour.

THE DIMINISHING BIRTH-RATE AND WHAT IS INVOLVED BY IT.

In an address, Taylor[16] shows that in the birth-rate of the United Kingdom compared with that of other countries during the last twenty years, no other nation has sustained so great a loss. The marriage rate in the United Kingdom during the same period was found to be slowly rising, so that the "birth loss" was necessarily due to causes operating in the married life of the population, and not simply due to celibacy.

He says the cause may be traced to the deliberate prevention of conception, and he takes the view that this is not only destructive to the future life of the nation, but seriously injurious to those who practice it. The child reared in greater comfort or comparative luxury, with no brothers or sisters of similar age to rub off its angles and selfishness, was ill-prepared for the succeeding battle of life, and it was very frequently the child of the larger family and poorer parents who pushed his way in front of him and elbowed him to the wall.

Attention was drawn to the present condition and statistics of France where, for fifty years, the birth-rate had been falling until the population had become stationary, or even less than stationary. During the last fifty years criminality had trebled in France, that of children and young people being specially remarkable, and particularly so regarding crimes of lust and prostitution. It was pointed out that after half a century of trial with an increasingly limited population, France showed more and more a lowered and still falling moral average, a lessening virtue or strength, and an increasing national neurasthenia which seemed to crave and to need the help of constant stimulation in order to face the ordinary routine of life. The future danger of this under a democratic form of government was considered and insisted on. So long as the race progressed, the people could be trusted with the powers of government, but when decadence had been going on for years, and even ages, what could be the final outcome of such democracy but anarchy and confusion?

The birth loss in the United Kingdom must be due to causes operating in the married life of its

[13] American Medicine, May 14, 1904, p. 783.

[15] Deutsche med. Woch., xxx, No. 1: Brit. Med. Jour., Mar. 5, 1904, p. 39, Epit.
[16] Brit. Med. Jour., v. 1, 1904, p. 427.

inhabitants. Therefore there was no reason to fear any high ideal of chastity or continence, and especially when this was associated with the care of those forces which go for the defence of the nation, and that child life which was its future hope. On the other hand, there was every reason to fear that debased ideal of married life, which was secretly and insidiously working for the ruin of the nation's power and for the destruction of its hope.

Insisting on the necessity of arousing the public conscience, and of aiming at a truer and braver conception of life, Taylor concluded by saying that he must confess when he heard of thoughtful men among the Boers in South Africa, military authorities in St. Petersburg, and Japanese in far Japan noticing and counting on their own racial increase, and comparing this with our own comparative stagnation, he would like, if he could, to sting his fellow countrymen into some proportionate sense of shame and duty.

RETROVERSION OF THE GRAVID UTERUS.

Herman[17] denies that retroversion of the gravid uterus brings with it dangers of abortion. He says when the uterus is large enough to become incarcerated under the sacral promontory, the patient has gone past the time for abortion. If retention of urine is allowed to go long unrelieved, so that cystitis and pyelitis are present, and the patient dying of uremia, abortion will probably precede death. If the uterus is roughly handled in violent attempts at replacement, such misusage may bring about abortion. But retroversion of the gravid uterus is not itself a cause of abortion, and causes no ill effects on the organ itself. The danger of retroversion of the gravid uterus comes in the fourth month from its causing retention of urine, and its only importance arises from its effect upon the bladder; its only dangers are those which directly or indirectly spring from retention of urine, as cystitis, peritonitis, rupture of bladder, pyelitis, and uremia. The one necessary treatment is the catheter, which, if used in time, is sufficient to relieve symptoms and prevent danger. Keep the bladder empty and the patient recumbent, and in over 90% of cases the uterus will right itself. If it does not, pregnancy will still go on, the uterus will enlarge, its anterior wall rising in the abdomen to accommodate the growing fetus. After a few days the bladder, urethra, and cervix uteri gradually accommodate themselves to their altered position, and retention of urine ceases.

He has never seen a case of retroversion of the gravid uterus that could not be pushed up. In such cases, after the bladder has been emptied, the uterus can be pushed up through the vagina, or under anesthesia with two fingers in the rectum. He sees no reason for abdominal section, as it can be beneficial only when the uterus is fixed by adhesions in a position for retroversion, a rare complication of pregnancy.

[17] Brit. Med. Jour., Apr. 16, 1904, p. 878.

ICHTHYOL IN PUERPERAL FEVER.

MacPherson[18] has used ichthyol in five cases of puerperal fever, three of which were desperate, and with excellent results in all. In these cases the uterus was first thoroughly irrigated with a bichloride (1 in 4,000) solution, and then packed with gauze soaked in equal parts of ichthyol and glycerine. In two of the cases, instead of ichthyol gauze, two drams of a 50% ichthyol watery solution were injected into the uterus. The improvement was very noticeable in each case. The irrigations and ichthyol applications were repeated in some of the cases, but the improvement which followed was attributed to the beneficial influences of ichthyol. He believes it is a valuable remedy.

He states the objection may be made that the packing had as much to do with the patient's improved condition as the ichthyol, but in two of the cases reported, no packing was used, and the drug was simply injected into the uterine cavity after free irrigation. One case of severe depression following the application of ichthyol to the cavity of the uterus has been reported, but no such untoward symptoms appeared in any of these cases. These patients were well stimulated with strychnine and ammonium carbonate at the time. Instead of any unpleasant symptoms arising, exactly the opposite were observed, the drug acting like a specific. Not only were the pulse and temperature reduced, rigors ceased, and discharge lessened, but patients had a feeling of well-being following the use of ichthyol, which was a pleasant contrast to the appearance of mental and physical suffering which one often witnesses in these cases.

PUERPERAL SEPSIS, NEW OPERATION FOR.

Chandler[19] recommends the following operation, which he says he has been performing for the past six years:

He makes an incision posteriorly to the cervix in the posterior vaginal wall, then passing a pair of long, blunt-pointed forceps, slightly curved, into the cervical canal, and up into the cavity of the uterus, he punctures the posterior wall of the uterus in the center, near the top of the uterus, and introducing with two fingers a piece or strip of iodoform gauze through the posterior vaginal opening previously made, he clasps the gauze with the forceps, drags it through the uterine wall and out through the vagina. He repeats this by puncturing the uterus on each side, but posteriorly and just above the middle of the body of the same, drawing the gauze through the openings as in the first.

He admits that it causes injury to the uterus, but says we do not hesitate to open other organs when infected, and experience in this operation is similar to operation in other parts. He claims that it is conservative, easily performed by the experienced, and that the mortality is lowered by the procedure.

BIOCHEMISTRY OF PREGNANCY.

Some interesting experiments have been conducted in this field by Opitz.[20] By the injection of human placental tissue freed from blood, into animals (rabbits, goats, heifers and horses), he secured a serum, which he calls "syncytiolytic," and which he applied in several cases of eclampsia. It was found to display an antitoxic power against the assumed syncytiotoxins, which the author believes are circulating in the blood in eclampsia and form one of its etiological factors. This process he explains as follows: As soon as the maternal blood penetrates the trophoblasts, cells from the periphery of the ovum find their way into the maternal blood and are carried away into various organs. These deported cells are destroyed sooner or later, under the action of cytolysins formed in the blood of the mother, and their disintegrated particles have a toxic action as foreign bodies. To neutralize these, another substance is produced in the blood, the "antisyncytiotoxin." Opitz has succeeded in reproducing this process in animals by injection of placental tissue, and their serum acquires the properties of an antisyncytiotoxin. The results of the application of this serum in eclampsia have encouraged the author to advise the preparation of this serum in marketable quantities. It has proven absolutely harmless, and the details of its action will be given in a later communication.

ECLAMPSIA.

Hirst [21] believes strongly in the nephritic origin of eclampsia. He says it is not true that women with nephritis are not predisposed to eclampsia. The reasons why a comparatively small percentage of them actually arrive at the convulsive stage are that abortion, miscarriage and premature death of the fetus is the rule in the nephritis of gravid women, and that the signs of toxemia appear so early and are so marked as often to call for the artificial termination of pregnancy.

Among the premonitory signs of eclampsia, there is nothing comparable to the presence of albumin in considerable and increasing quantities in the filtered urine. It is true that a certain proportion of cases occur without precedent albuminuria, but their proportion is not nearly so large as one would infer from the report of sporadic cases. It is a clinical rule, with few exceptions, that albuminuria precedes the other signs of gestational toxemia, that the gravity of the woman's condition can be measured by the steady increase in the amount of albumin in spite of treatment, and that a steady and rapid increase of albumin is the most certain and constant premonitory sign of eclampsia that we possess at present.

The preventive treatment is based by every one on the theory of kidney inadequacy. It consists, as we all know, of a milk diet, diaphoresis, diuresis, and catharsis, with extra precautions against chilling the skin. The use of thyroid extract as proposed by Nicholson is still on trial. He does not believe in too rapid evacuation of the uterus, nor in cesarean section. He prefers to bring on labor slowly than resort to forced delivery, employing actively the elimination treatment. For convulsions, eliminate the poison and quiet the nervous irritability. It is generally agreed that normal salt injections, sweating and purgatives are the most reliable eliminants. Venesection may be classed among these, but he rarely uses it now. He thinks opium interferes with elimination, and a large dose may cause fatal poisoning in view of the inactivity of the kidneys. For the relief of arterial tension, he would use veratrum viride. He closes by urging the advantages of hospital treatment for such cases, as the mortality is less than one half what it is in private practice.

THYROID TREATMENT IN ECLAMPSIA.

The success of thyroid treatment in two cases reported confirms Nicholson's [22] statements in regard to the efficacy of thyroid extract in this affection. Baldovsky found that the convulsions abated under its influence, while it also regulated the eliminating functions of the kidneys. The urine increased in quantity, and the proportion of albumin rapidly diminished. He used narcotics in combination with it, and recommends this practice, as they keep the convulsions in check. His dosage was the same as Nicholson's, a .3 gm. tablet of thyroidin three or four times a day. The albumin nearly vanished in the first case within four hours of the second dose, which had been given two hours after the first one, dropping from more than 4 to a proportion of less than .5.

IMMEDIATE DELIVERY THE BEST TREATMENT IN ECLAMPSIA.

Bumm [23] says that his observations for the last two years have produced the conviction that in the treatment of the eclamptic soon after the first attack, while the pulse is good and the lungs intact, we shall obtain the best results as a rule by the immediate emptying of the uterus, and that through following this principle of treatment, the mortality, varying under other methods from 12% to 30%, may be reduced to 5%. A considerable proportion of his patients were brought to the hospital in coma, due in at least a third of the cases to the do-nothing policy and the old morphine therapy. If the eclamptic poisoning has already caused necrotic changes in the liver and kidneys and apoplectic effusion of the brain, or if in the course of long-enduring coma, severe lesion of the lungs has occurred, delivery can bring no help. For which reason he all the more insists upon immediate delivery before it is too late.

SPINAL PUNCTURE FOR ECLAMPTIC CONVULSIONS.

Helme [24] agrees that eclampsia is probably due to the presence of toxic material in the blood, and

that the first indication in treatment is to prevent accumulation and to assist elimination. He suggests, however, that eclampsia may be due to increased cerebrospinal tension, as the clinical aspect of a case indicates intracranial pressure, and convulsions increase the pressure by causing congestion of the cerebral vessels. For relief of this condition he suggests tapping the spinal canal in the lumbar region, and reports one successful case done under chloroform. A drachm and a half of cerebrospinal fluid escaped rapidly, as if under considerable pressure, and not drop by drop, as in health. He suggests that the treatment should be tried in suitable cases, and has only brought it up now because of the importance of the subject.

Reports of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

ANNUAL MEETING AT ATLANTIC CITY, NEW JERSEY, JUNE 2, 3 AND 4. 1904.

(Continued from No. 9, p. 248.)

FIRST DAY — (Continued).

FACIAL ASYMMETRY AS A CAUSE OF DEFORMITIES OF THE NASAL SEPTUM.

DR. HENRY L. SWAIN of New Haven, Conn., presented this paper as a sequel to or continuation of his paper read at the last annual meeting on "The Arch of the Palate," which last paper gave the results of a search for some possible relation between the shape of the skull and the arch of the palate, the whole study being prompted by his doubts as to the importance of the influence of adenoids, and the consequent nasal obstruction, upon the narrowing and arching of the palate.

The present paper was the result of much work in the way of measurements of the vertical and horizontal diameters of the posterior cloacae, and observations on the asymmetry of the two sides of the face and head in certain races and individuals, most of the work being done on Hawaiian and Flathead Indian skulls.

His conclusions, briefly, were that adenoid obstruction does not always and may never cause over-arching of the palate; that over-arching of the palate does not always produce bends of the septum; that over-arched palates and bent septa often occur together, and each is more frequent in skulls which are leptoprosopic; that leptoprosopic skulls and faces almost never exist in a marked degree without some distortion or over-arching of the palate and changes in the nasal cavity; that in a young child about to develop into marked leptoprosopia, pronounced nasal stoppage by adenoids cannot fail to *add* to the degree of deformity; that if the first teeth are removed early and the dental arch disturbed, then the palate will move easily, become narrowed and pointed in its own arch; and that the whole tendency is more often inherited than acquired.

INTRATRACHEAL INJECTIONS.

DR. THOMAS HUBBARD of Toledo, O., read a paper with the above title, awarding the claim of priority to Botey of Barcelona for putting the method upon a practical basis, although much had been done by others before Botey, notably Dr. Howard Green of New York. After detailing the history of the development of the procedure, the author spoke of the technique and the indications for its use. The intratracheal injections must not be used in the acute hyperemic stage of any inflammation, but must be withheld until the acute symptoms have subsided and the general systemic conditions are favorable to recovery, *e. g.*, in convalescence from acute bronchitis, taking the place of the usually administered "stimulating expectorants," and thus also relieving the gastro-intestinal tract of the disturbing influence of cough mixtures in syrups "*ad nauseam.*" The idea of treatment is essentially local; absorption for systemic medication is not the object of the method at all. He mentioned oil as the best menstruum, and the best medicaments to be used are guaiacol and menthol, in 1 to 3% solutions. In chronic bronchitis, bronchial asthma, bronchiectasis, fetid bronchitis, and in tuberculosis, the injections are very useful, but of course not to be urged to the exclusion of general treatment, only as valuable adjuvants. The injections are made by means of various cannulæ and tracheal syringes, and the utmost care must be used not to touch the epiglottis; if that is avoided, the injections are well tolerated by most patients. If possible, they should be made with the aid of a laryngeal mirror.

THE COMPENSATORY ACTION OF CERTAIN OF THE LARYNGEAL MUSCLES SEEN IN CASES OF VOCAL DISABILITY.

DR. CLARENCE C. RICE of New York read this paper, and gave many interesting facts about the results, in young voices, of overuse, or misuse, of some muscles of the larynx by faulty methods of instruction in singing, and the compensatory action of other muscles in doing the work of the damaged ones. His results may be stated in summary as follows:

(1) There exists throughout the entire muscular system of the body the intention and habit of one group to render assistance to any other group of muscles which may be temporarily or permanently inefficient.

(2) That such compensatory service is more readily appreciated in the larynx than elsewhere, because its technique may be observed with the laryngeal mirror.

(3) That the weaker of the laryngeal muscles are very easily fatigued by too rapid training or by over training, and that it is the habit of the stronger muscles immediately to offer their assistance.

(4) That although this compensatory action is wonderful from a physiological point of view, it is unfortunately accomplished at the expense of any great success in singing.

SEQUEL OF THE CASE OF LARYNGEAL PERICHONDRITIS AFTER TYPHOID, REPORTED TO THE ASSOCIATION IN MAY, 1903.

DR. EMIL MAYER of New York reported the above case in full at the last annual meeting, at which time the patient was wearing an intubation tube, which had been put into the larynx after a previous emergency tracheotomy.

With the tube in place the patient had made a trip to Europe, and after four months' continuous wearing it was removed; a few days later there was some dyspnea, and a small tube was inserted and left in for one week and then removed. Since then nine months have elapsed with no dyspnea, no discomfort, full return of voice, though of deeper pitch than before, and in all respects a return to normal conditions in the larynx. The author believes this to be the first case of the kind cured by intubation.

DISCUSSION OF NEUROSES OF THE UPPER AIR TRACT, EXCLUSIVE OF THOSE DUE TO DIPHTHERIA AND TO ORGANIC DISEASE.

"Neuroses of the Nose," by DR. G. HUDSON MAKUEN, Philadelphia; "Neuroses of the Pharynx,"

by DR. F. E. HOPKINS, Springfield; "Neuroses of the Larynx," by DR. EMIL MAYER, New York.

NEUROSES OF THE NOSE.

DR. MAKUEN presented this paper in the discussion, dividing the neuroses into two classes, the sensory and the reflex, giving a full list of the usual well-known conditions included under each class.

In regard to the second class the author expressed himself as somewhat skeptical, and felt that many rhinologists had perhaps "found what they most desired to find" in very many cases. But he still felt that there were some undoubted cases of reflex symptoms due to nasal irritation, and thought that the operative measures suggested for their cure were such as to add to the comfort and happiness of the patient in other ways, even if they did not cure the neuroses. After speaking of the commonly described "reflex arc" and its action, he said that a "pathological reflex always presupposes one of two things: either a disturbance in some portion of the reflex arc, or some unusual peripheral irritation; and a disturbance in the reflex arc renders the nervous system unstable, a condition known as hysteria, or as neurasthenia." He then emphasized the fact that, while a peripheral irritation in the nose may be the origin of a pathological reflex, we must keep in mind the fact that sooner or later we have to deal with an unstable nervous system.

The reflex neuroses of undoubted nasal origin he stated as sneezing, cough, spasm of the glottis and asthma, the most important being cough and asthma.

NEUROSES OF THE PHARYNX.

Dr. F. E. HOPKINS of Springfield read this paper, classifying the neuroses as: Abnormalities of sensation, neuralgia, reflex neuroses, spasmodic disturbances, vascular neuroses. He discussed anesthesia, hyperesthesia and paresthesia, and referred to that rare condition, chorea pharyngis, citing Lambert Lacke's typical case, published (*Laryngoscope*) in June, 1898.

He noted that nearly all the patients exhibiting these neuroses are neurasthenic, and while advising some treatment of the local lesions when found, felt that most reliance must be placed upon treatment of the general health.

NEUROSES OF THE LARYNX.

DR. EMIL MAYER of New York read this paper classifying the neuroses under the following heads:

(1) Motor disturbances of a hyperkinetic nature: The spasmodic affections of the larynx.
(2) Stammering.
(3) Status lymphaticus and sudden deaths.
(4) Motor paralyses.

The author merely mentioned, without discussion, the various sensory disturbances, such as anesthesia and hyperesthesia. Under the spasmodic affections he described at length laryngismus stridulus, congenital stridor, spasm of the glottis, chorea of the larynx, laryngeal nystagmus, laryngeal vertigo and dysphonia spastica. Stammering, the author claimed, to be entirely an acquired defect, not congenital nor hereditary, and its treatment a process of most careful, patient, painstaking *education*.

He spoke particularly of the "status lymphaticus" and its connection with the sudden death caused at times by spasm of the larynx, especially in explanation of the deaths from anesthesia in operations for adenoids, in which cases the "status lymphaticus" is practically always present. With his description of the various motor paralyses, he strongly advocated electricity in the treatment.

ESOPHAGOSCOPY AND BRONCHOSCOPY. KILLIAN'S OPERATION. REPORT OF TWO CASES.

DR. E. FLETCHER INGALS of Chicago, Ill., read this paper, speaking first of the recent development of the two procedures, as demonstrated by Killian in 1902. The author stated that, although "the ease with which foreign bodies can usually be removed from the trachea and often from a main bronchus, after tracheotomy, makes the latter operation preferable in most cases, when the diagnosis is in doubt or when the foreign body has passed into one of the divisions of a bronchus, bronchoscopy affords a means not only of diagnosis, but of successful operation, infinitely superior to transthoracic bronchotomy." In connection with any of these procedures, the location of the foreign body by the x-rays is, of course, desirable. The author detailed two interesting cases, illustrated by radiographs, one of an ornamental pin in the esophagus, and the other a long, straight pin in a branch of a bronchus, both successfully extracted by means of Killian's instruments.

(To be continued.)

Recent Literature.

Obstetric and Gynecologic Nursing. By EDWARD P. DAVIS, A.M., M.D., Professor of Obstetrics in the Jefferson Medical College and in the Philadelphia Polyclinic. 12mo. volume of 402 pages, fully illustrated. Second edition, thoroughly revised. Philadelphia, New York, London: W. B. Saunders & Company. 1904.

Besides the usual chapters on obstetric and gynecologic nursing, this edition of Dr. Davis' book contains chapters on the disorders of infancy, on cancer, on mental diseases complicating pelvic disorders, and on venereal or specific disease; the appendix having a useful dietary and an article on the preparation of surgical supplies.

The author has had the advantage of assistance by the chief nurses of the Jefferson Maternity and the Philadelphia Hospital and the dietician and directress of the Jefferson Medical College Hospital, so that although the subject is treated from the standpoint of the physician instructing nurses there are many practical suggestions which originated in the experience of the nurse instructor.

The nurse is told not only what to do under given conditions but also what the physician does and why he does it. Excellent advice is given as to the responsibilities which should not be assumed by the nurse, *e. g.*, "a vaginal injection before labor should never be given without the precise order of the doctor," and "the nurse is not to prescribe an infant's food."

The use of such terms as "sapremia" and "hypodermoclysis" call for a glossary, which the book does not have, and we think it would be an improvement if there were a chapter on the administration of anesthetics, as nurses are so frequently called on to anesthetize at least part of the time, both during labor and in gynecologic operations.

Not only nurses but recently graduated medical men could learn a great deal by a perusal of this book; it is to be highly recommended.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 8, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 Bromfield Street, Boston, Mass.

SUPPLY AND DEMAND IN MEDICAL EDUCATION.

That a condition of equilibrium has not yet been reached in educational matters in this country is apparent. It has been the experience in most of our large institutions of learning that each year sees a greater number of students than the preceding, and, although there may be a certain fluctuation in the various departments, the tendency has constantly been toward increased numbers of matriculants. This is no doubt natural in a country, the resources of which are far from complete development, with the population of its large cities constantly augmenting. As a consequence of these facts the extension of university facilities has likewise developed with great rapidity in an attempt to keep pace with the increasing demand. It must, however, be recognized that the time is coming when a more definite equilibrium will be attained, and each succeeding year will see a smaller increase of students.

The tendency to medical education of late years has been to extend to a quite extraordinary degree the facilities for instruction, with the apparent expectation that the influx of students would go on increasing in like proportion. Whether or not this will be the case we do not predict, but it is evident that all over the country, following in a measure each other's example, our larger universities have extended the medical facilities to such a degree that opportunities for the completest medical education are prepared for a long time to come. The leading universities throughout the country are recognizing the position which medical instruction should take in the general university curriculum. Funds have been provided from various quarters and buildings erected, it sometimes appears, rather regardless of their actual need. The development of laboratory instruction has, in a measure, made this demand, but we are convinced that in all our larger medical centers there is at the present time laboratory opportunity which is frequently in excess of the demand.

It is evident that our medical schools must have students, and that the foundation of medical instruction lies with those now entering upon the study of this profession. It is, therefore, worth considering that, for example, out of last year's graduating class at Harvard about twenty men signified their intention of studying medicine, whereas about six times that number had decided upon the study of law. This showing is certainly somewhat surprising, especially in view of the widening scope of medical education and the very great competition in the practice of law. We are under the impression that the disparity between those taking up the law and medicine, certainly in this community, is increasing to the detriment of medicine. The reasons for this are no doubt subtle and far-reaching; we have no intention of discussing them at length at this time, but it behooves those interested in medical education to bear the facts in mind, and to realize that medical schools of the very first order are being developed in various parts of this country which are likely, with their present equipment, to fill the requirements for many years to come. In our enthusiasm for one department of learning we are apt to ignore the fact that many other departments and many other spheres of usefulness are likewise opening for men about beginning their careers, and that medicine must compete for its students as do other callings. In the meantime the balance between facilities for study and the students demanding such facilities must be maintained with skill and caution.

THE INFLUENCE OF HYSTEROPEXY ON FUTURE PREGNANCIES.

At the recent meeting of the French Congress of Gynecology the important question of the influence of hysteropexy on future pregnancies was lengthily discussed both by the members and in the report of Oui. Considering the large number of procedures employed for fixation of the uterus, statistics are of little avail, but by attentively studying the way in which abdominal or vaginal fixation acts one may arrive at some conclusions.

The first question to solve is the influence of anterior abdominal hysteropexy on the duration of pregnancy. The observations of Laroyenne, Condamin, Sinclair, Negri, Terrier, Pinard, Routier and LeFort show beyond all doubt that complete fixation of the uterus is perfectly compatible with the evolution of pregnancy. To what extent such or such procedure of fixation or of suture of the uterus to the anterior abdominal wall may be held responsible for the interruption of pregnancy is a question difficult to elucidate. Demelin believed that Olshausen's technique is the one most likely to produce miscarriage on account of the implantation of the sutures in the neighborhood of the vasculonervous pedicles, and the same may be said of the procedures with buried sutures on account of the greater solidity which they give to the uteroparietal adhesions. According to Oui the greatest danger to the evolution of pregnancy is in those cases where the fundus uteri is firmly fixed to the anterior abdominal wall.

As to the influence of hysteropexy on the presentation, the following figures are of interest. Out of ninety-four labors in patients having previously had a hysteropexy done, Demelin found ninety-four vertex presentations, three shoulder and one breech presentation, while Kustner reports three abnormal presentations out of a total of ninety cases.

These figures would appear to show that hysteropexy does not have any marked influence on the presentation, but on the other hand Pinard in 1899 observed one breech and three shoulder presentations out of six labors in patients who had had hysteropexy performed. The only astonishing thing is that faulty presentations are not more frequent after anterior fixation of the uterus when one recalls the importance of defective engagement of the fetus in the genesis of shoulder presentations. In some cases, the physiognomy of the labor is distinctly changed and delivery difficult.

Some statistics show the great frequency of normal labors. Schwartz has had seven patients who had nine pregnancies, seven of which went to term and were delivered spontaneously, while Richelot records two, Leguen three, Dickinson two and Jarman three normal labors after hysteropexy. Grandin reports two normal labors, but the uterus was again found retroflexed after the labors.

Besides rigidity of the cervix and the possible obstruction of the superior strait by the anterior abdominal wall or hypertrophied fundus uteri, one should remember that rupture of the uterus may occur, due both to the resistance met with by the fetus during its passage and the great thinness of the posterior uterine wall; three such instances were reported at the New York Obstetrical Society in 1901.

Generally speaking, it may be said that in the great majority of cases hysteropexy has no ill effect on the evolution or progress of the labor, but, as has been pointed out by Pinard, all abdominal hysteropexies do not give the same result and do not have the same consequences as far as future pregnancies and labors are concerned. Thus one sees certain operative procedures give rise to a large number of serious dystociae, while others, on the contrary, are quite inoffensive.

Certain procedures appear to possess inconveniences peculiar to them. The fixation of the fundus, especially when made near the pubic bone, is particularly bad because it places the uterus in an exaggerated anteversion, causes an extreme development of the posterior uterine parietes and may occasionally produce an obstruction of the superior strait by the anterior wall or the hypertrophied fundus uteri. It is also to be remarked that in those cases where the adhesions have remained solid, an indirect fixation by a pedicle formed by the adnexa has been known to produce a torsion of the gravid uterus on its longitudinal axis. From these facts it would appear indicated to place the uteroparietal sutures only in the anterior wall of the organ below the line of the tubes and not to include too much surface of the uterine wall.

As to vaginal hysteropexy it may be said that it frequently gives rise to pain and disturbances in the micturition. Vaginal fixation appears to have an unfavorable influence on pregnancy, and of ninety-five pregnancies followed to their end, Demelin observed nineteen miscarriages, or about 22%. These statistics were reported in 1896, and during the same year Kustner reported eighteen miscarriages out of a total of forty-eight pregnancies, making 37%, one of which was followed by retention of the placenta. It is quite true that since the above statistics have been published Dührssen has made public the marvellous record of seventy pregnancies occurring after his latest method of vaginal hysteropexy all of which, with one exception, ended favorably. Dührssen's statistics are the only ones that have ever been published with such an excellent showing, both as regards pregnancy and labor.

The prognosis of vaginal hysteropexy would

consequently appear distinctly less favorable as far as pregnancy is concerned when compared to abdominal fixation, and it is certain that in the former the anteversion and flexion are far more pronounced than in the latter condition. It is also quite certain that more serious cases of dystocia are met with in Germany, where vaginal hysteropexy has become the ordinary procedure.

The last statistics of Dührssen may perhaps induce some to adopt his technique, but it is probable that many operators will find the means of fixation too weak in this method, and the result may be that more solid fixation will be looked for, which is obtained in other techniques, and serious dystocia will ensue.

MEDICAL NOTES.

Sir John Simon's Estate. — The late Sir John Simon's estate, valued at upwards of $130,000, after certain annuities and a life interest are paid, reverts to St. Thomas's Hospital, London.

Paris Academy of Medicine. — Recent elections as foreign corresponding members of the Paris Academy of Medicine are Major Ronald Ross of Liverpool and Dr. Weir Mitchell of Philadelphia.

Arrival of Professor Wassermann of Berlin. — A recent arrival from Europe was Professor Wassermann of Berlin, whose reputation rests chiefly on his work on immunity. He is to deliver a certain number of lectures in St. Louis, and also to serve as one of the judges of the medical exhibit.

Death of William Weightman. — William Weightman, of the well-known firm of manufacturing chemists of Philadelphia, has recently died at the age of ninety. His interest lay chiefly in the manufacture of quinine and morphine, and it is stated that the foundation of his ultimately great fortune was laid by the sale of quinine to the Union and Southern armies during the Civil War.

Hospital Development. — The proposed new Bellevue Hospital, plans of which have been offered, bids fair to take second place if the design for the new hospital in Vienna, which has already been begun, be carried to completion. It is stated that there will be thirty-two separate sub-hospitals within the general enclosure, and eighteen separate pavilions, with 2300 beds for patients. *American Medicine* states that in the clinics for infectious disease the possibility of infection will be reduced to a minimum by the separation of the instructor and students from the patient by glass partitions. It is estimated that the cost will be eight million dollars.

Infrequency of Typhoid in Chicago. — According to the *Bulletin* of the Chicago Health Department, one of the most gratifying features, next to the continued low mortality among infants and children, is the infrequency of typhoid fever in that city. This disease always shows a seasonal increase, beginning in July and culminating in October. The increase has averaged for thirty years more than 63% in August over the rate of the first six months of the year, which would make the typhoid deaths for this month about 47. During the twenty-seven elapsed days there have been but 26 deaths from typhoid fever reported, and the total for the month is not likely to be more than 31 or 32. In August, 1903, there were 51 deaths from typhoid.

Prof. Oscar Hertwig, Director of Medicine and of Philosophy, Director of the Anatomico-Biological Institute and Member of the Academy of Sciences, according to the *British Medical Journal*, has been elected Rector of the University of Berlin for the coming year. Of the ninety-five rectors of that seat of learning, he is the sixteenth who has been chosen from the Faculty of Medicine. Professor Hertwig was Dean of that Faculty in 1894–95. The Dean of the Medical Faculty for 1904–05 is Prof. Johannes Orth, the successor of Rudolf Virchow in the Chair of Pathology.

Fourth Pan-American Medical Congress.— President Amador of the Republic of Panama has appointed the following officers of the Fourth Pan-American Medical Congress, to be held in Panama the first week in January, 1905:

Dr. Julio Yeaza, President; Dr. Manuel Coroalles, Vice-President; Dr. Jose E. Calvo, Secretary; Dr. Pedro de Obarrio, Treasurer. There will be but four sections: Surgery, Medicine, Hygiene and the Specialties, to which the following officers were appointed: Surgical Section: Maj. Louis LaGarde, President; Dr. E. B. Harrick, Secretary. Medical Section: Dr. Moritz Stern, President; Dr. Daniel R. Oduber, Secretary. Section on Hygiene: Col. W. C. Gorgas, President; Dr. Henry E. Carter, Secretary. Section on Specialties: Dr. W. Spratling, President; Dr. Charles A. Cooke, Secretary.

BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon Sept. 7, 1904, there were reported to the Board of Health of Boston

the following cases of acute infectious diseases: Diphtheria 43, scarlatina 10, typhoid fever 50, measles 3, smallpox 0.

STRIKE AT HARVARD MEDICAL SCHOOL BUILDINGS. — Owing to the common cause of the employment of a non-union mason, it is stated that a certain number of bricklayers have struck, who were at work on the new buildings of the Harvard Medical School. Owing to the dependence of other workmen upon these, temporary cessation of the work has been necessitated.

SMALLPOX IN NORTH ADAMS, MASS. — It is stated that the Board of Health of North Adams, Mass., has closed schools and other much frequented buildings because of the existence of smallpox in the city. Upwards of thirty-five cases have been reported and stringent measures have been taken looking to disinfection of mail matter.

A CENTENARIAN. — It is stated that Mrs. Betsy Dodge of Everett, Mass., has recently died at the age of one hundred and one years. For ten years past her general condition of health has been poor.

CHANGE IN COURSE FOR NURSES, MCLEAN HOSPITAL. — Beginning Oct. 1, 1904, there will be a change in the training school for women nurses, at the McLean Hospital, Waverley, Mass.

The length of the course will be increased from two to two and a half years, more instruction will be given and the nurse will have more time for study. She will be given courses in anatomy, physiology, hygiene, bacteriology, urinalysis, hydrotherapy, electrotherapy, massage, physical exercise, the dispensing of drugs, housekeeping, cookery, general nursing, and the nursing of cases of nervous and mental disease. Instruction will be given by means of textbooks, lectures and, where practicable, by demonstrations and actual work in the dispensary and the laboratories, as well as in the wards of the hospital.

During a half of the first school year the pupil will be given no more work on the wards than is necessary to put in practice the demonstrations received in the course of instruction, — perhaps two hours daily. For this time it will be practically a boarding school for the pupil nurse.

The change will necessitate the employment of more nurses and will be an additional expense to the hospital, notwithstanding a reduction of $5 in the monthly pay.

The length of the course for men nurses will continue for the present to be two years.

NEW YORK.

BEQUEST. — The new Amsterdam Eye and Ear Infirmary is reported to be the recipient of $10,000 by the will of the late William H. Crawford who died recently in New York.

ST. LOUIS MEDICAL REVIEW UNDER NEW EDITORSHIP. — Dr. Kenneth W. Millican has resigned his position as associate editor of the *New York Medical Journal*, which he has held since April, 1898, in order to assume the editorship and entire charge of the *St. Louis Medical Review*.

A NEW HOSPITAL. — A new hospital, to be known as the Brooklyn Samaritan Hospital, is shortly to be established at Fifteenth Street and Fourth Avenue in that borough. This institution is the outgrowth of the dispensary work of the Fifteenth Street Baptist Church, but it will be nonsectarian in character.

VEREINIGUNG ALTER DEUTSCHER STUDENTEN IN AMERIKA. — The union of Old German Students in America will give a "Commers" in honor of the German scientists who will visit the St. Louis Congress of art and science. Most of the guests are medical men. The date which has been fixed upon is Oct. 8, at the Arion Hall in New York.

INTERNATIONAL SOCIETY OF CHEMICAL INDUSTRY. — The first annual meeting in America of the International Society of Chemical Industry is being held this week, Sept. 7 to 12, at the Chemists' Club and Havemeyer Hall, Columbia University. The president of the society, Sir William Ramsay, K C B., the eminent English chemist, and a party of fourteen other noted foreign scientists arrived by the steamship "Baltic" on Sept. 1 to attend the meeting.

REPORT ON "SLOCUM" DISASTER. — On Aug. 31, the committee appointed by the mayor to administer the funds subscribed for the relief of the sufferers from the "Slocum" disaster of June 15 made a report of its work. The total contributions amounted to $124,205.80, and with the exception of $20,000 set apart for the future needs of those who were made to a greater or less degree dependent, the funds have now been expended. Among the expenditures was the sum of $1,264 for medical attendance and supplies furnished to 38 families. The list of dead is officially placed at 958. In all, 897 bodies were identified and 61 were buried without identification. There were represented on the "Slocum" on the day of the disaster 590 families, and

three fourths of these, or 437 families, were aided by the committee. The committee buried 705 persons belonging to 388 families, at an expense of $81,280. The report gives the first authentic information of the losses by various families. One hundred and twenty men lost their entire families. Of these, ten lost wife and three children; three, wife and four children, and one, wife and five children. There were twelve families in which orphan children were left, the number of orphans being 27 in all.

Official Interpreter at Bellevue Hospital. — Ermenegeldo Zordan, a professor in the University of Padua who is now in New York on a two years' leave of absence from the University, has been appointed official interpreter at Bellevue Hospital, an office that has been needed for many years. He is stated to be one of the most accomplished linguists who ever came to America, speaking English, German, Italian, Spanish, Polish, Yiddish and modern Greek as well as he does French, which is his native tongue. Professor Zordan has been engaged for seven years in writing a work on the literature and customs of the leading nations of the world, and, not being wealthy, finds it necessary to have some employment while pursuing his American studies.

August Mortality Report. — The mortality reported in the city during the month of August represents an annual death-rate of 18.63, as against 21.86 in July. This is an excellent showing for the season, though not equal to that of August, 1903, when the death-rate reached the low figure of 17.28. The corrected death-rate for August of this year, excluding non-residents and infants under one week old, is 17.84. Among the diseases in which there was a diminished fatality were the following: The weekly average of deaths from diphtheria and croup decreased from 29.75 in July to 26.75 in August; the weekly average from scarlet fever, from 7.75 to 2.75; from measles, from 10.75 to 6; from whooping-cough, from 4.75 to 3.5; from epidemic cerebrospinal meningitis, from 26 to 20.75; from pneumonia, from 53.75 to 43.5; from broncho-pneumonia, from 46 to 43.75; from acute bronchitis, from 15.25 to 14; from pulmonary tuberculosis, from 152 to 144; from diarrheal diseases, from 467.25 to 318; from diarrheals in children under two years of age, from 427.25 to 286; and from Bright's disease and nephritis, from 113.5 to 97. Among the diseases which showed an increased mortality were the following: The weekly average of deaths from typhoid fever increased from 11.25 to 19.5; from cancer, from 48 to 49.75; and from organic heart diseases, from 75.25 to 87.75.

Obituary.

HENRY TUCK, M.D.

Dr. Henry Tuck of New York died at his summer home, Seabright, N. J., on Sept. 2, in the sixty-third year of his age, from Bright's disease. He was born at Barnstable, Mass., the son of a physician, and was graduated from the Harvard Medical School in 1867. Before taking his degree Dr. Tuck served as Acting Assistant Surgeon in the army in 1865, during the campaign preceding Lee's surrender at Appomattox. After his graduation he pursued his studies in Europe, and on his return practiced for ten years in Boston. Dr. Tuck was a well-known authority on life insurance. In 1878 he removed to New York, having been appointed one of the Medical Directors of the New York Life Insurance Company. In 1883 he was made second vice-president of that company, and in 1885, first vice-president, a position which he held up to the time of his death. He was twice married, his first wife being a daughter of William H. Beers, president of the New York Life Insurance Company, and his second, Miss Eleanor Hammond of Chestnut Hill, Mass., who, with several children, survives him.

Miscellany.

DR. WALTER REED AND THE PANAMA SANITARY OUTLOOK.

In the current number of the *Medical News* the editor remarks upon the sanitary outlook in Panama, and pays the following tribute to the late Dr. Walter Reed. After commenting in some detail upon the question of yellow fever and malaria, and the work which has led up to their etiological relationship to the mosquito, the editor closes as follows:

"All this looks simple enough now. The very favorable outlook, however, is due entirely to the work of one man, Dr. Walter Reed, who, in his quiet, unassuming way, accomplished as much for medicine as did Jenner, Lister or Pasteur. His greatest monument will undoubtedly be the fact that the canal at Panama will be finished without the awful loss of life that would otherwise be unavoidable. It is only proper and befitting his position as an American medical man that another and more formal monument to him should proclaim to admiring countrymen how much the fellow members of his profession appreciate the work that was so successfully accomplished by this compatriot whose untimely death cut off one of the most distinguished physicians of his generation, but whose memory will remain for all time as one of the glories of American medicine."

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, AUGUST 27, 1904.

Deaths reported, 3,216; under five years of age, 1,200; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,179; acute lung diseases 198, consumption 344, scarlet fever 7, whooping cough 15, cerebrospinal meningitis 22, smallpox —, erysipelas 3, puerperal fever 8, measles 6, typhoid fever 74, diarrheal diseases 653, diphtheria and croup 37.

From whooping cough, New York 6, Chicago 2, Philadelphia 2, Baltimore 1, Pittsburg 4. From measles, New York 4, Philadelphia 1, Pittsburg 1. From scarlet fever, New York 2, Chicago 2, Baltimore 2, Pittsburg 1. From cerebrospinal meningitis, New York 17, Baltimore 1, Pittsburg 1, Worcester 2, Weymouth 1. From typhoid fever, New York 27, Chicago 8, Philadelphia 8, Baltimore 4, Pittsburg 14, Providence 2, Somerville 2, Boston 1, Fall River 1, Lowell 1, Lawrence 1, New Bedford 1, Malden 1, Chicopee 1, Marlborough 1, Gardner 1. From erysipelas, New York 1, Philadelphia 1, Worcester 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending Aug. 13, the death-rate was 22.1. Deaths reported 6,482; acute diseases of the respiratory organs (London) 47, whooping cough 74, diphtheria 47, measles 122, smallpox 3, scarlet fever 28.

The death-rate ranged from 6.8 in South Shields, to 37.7 in Liverpool; London 21.4, West Ham 30.6, Brighton 12.8, Plymouth 13.7, Bristol 15.2, Leicester 17.4, Nottingham 28.1, Bolton 13.4, Manchester 23.6, Salford 28.0, Bradford 18.3, Leeds 23.9, Hull 31.2, Sheffield 21.2, Cardiff 16.6, Rhondda 31.1, Wigan 35.7, Merthyr Tydfil 22.2, Southampton 15.3.

METEOROLOGICAL RECORD.

For the week ending August 27, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 3, 1904.

J. E. PAGE, past assistant surgeon. Detached from the "Montgomery" and ordered to the "Puritan," then home and granted leave for one month.

H. T. NELSON, JR., acting assistant surgeon. Ordered to duty at the Naval Hospital, Washington, D. C.

J. J. SNYDER, past assistant surgeon. Detached from the "Maine" and ordered to the "Kearsarge."

F. W. BRECK, pharmacist. Appointed a pharmacist from May 20, 1904.

J. FLINT, assistant surgeon. Detached from the Naval Hospital, Boston, Mass., and ordered home, and resignation as an assistant surgeon in the navy accepted, to take effect September 6, 1904.

N. T. MCLEAN, assistant surgeon. Detached from the Naval Recruiting Station, Buffalo, N. Y., and ordered to the Naval Hospital, New York, N. Y.

RECENT DEATH.

ELBRIDGE GERRY SIMONS, M.D., of Ripley, Chautauqua County, N. Y., was killed on September 1, at Glenville, a suburb of Cleveland, Ohio, by being struck by a Lake Shore freight train.

BOOKS AND PAMPHLETS RECEIVED.

The Meaning of a Modern Hospital. By W. Bruce Clarke, M.A., M. B. Oxon., F.R.C.S. New York, London and Bombay: Longmans, Green & Co. 1904.

On the Local Application of Solutions of Saline Purgatives to the Peritoneal Surfaces of the Intestine. By John Bruce MacCallum. Berkeley: The University Press. 1904.

University of California Publications. Physiology. On the Action of Saline Purgatives in Rabbits and the Counteraction of their Effect by Calcium (Second Communication). By John Bruce MacCallum.

Manual of Intragastric Technique. Practical Lessons in the Use of Apparatus for the Diagnosis and Treatment of Diseases of the Stomach. By George Herschell, M.D. Lond. Illustrated. London: Henry J. Glaisher. Chicago: W. T. Keener & Co.

The Health Scholarship Prize Essay on The Development and Anatomy of the Prostate Gland, together with an Account of its Injuries and Diseases and their Surgical Treatment. By W. G. Richardson, M.B., B.S., F.R.C.S. Illustrated. London: J. & A. Churchill. 1904.

Radiotherapy and Phototherapy, including Radium and High-Frequency Currents, Their Medical and Surgical Applications in Diagnosis and Treatment. For Students and Practitioners. By Charles Warrenne Allen, M.D., with the co-operation of Milton Franklin, M.D., and Samuel Stern, M.D. Illustrated. New York and Philadelphia: Lea Brothers & Co. 1904.

The Medical Epitome Series. Surgery. A Manual for Students and Practitioners. By M. D'Arcy Magee, A.M., M.D., and Wallace Johnson, Ph.D., M.D. With an Appendix on X-ray Work in Surgery. By Edward O. Parker, A.M., M.D., Series edited by V. C. Pedersen, A.M., M.D. Illustrated. Philadelphia and New York: Lea Brothers & Co. 1904.

OBSTRUCTIVE RENAL RETENTION WITH ANURIA, AND ITS TREATMENT.*

BY FRANCIS S. WATSON, M.D., BOSTON.

THIS communication deals with those forms of renal retention only with which anuria is associated, and which originate in complete closure of the ureter or of the outlet of the renal pelvis.

As used here, anuria is intended to denote the reduction of the urinary secretion to a few drops in the course of each twenty-four hours; that is to say, the anuria which is termed *absolute*.

The phenomena which are observed in the kidney when its urinary outflow is completely obstructed are as follows:

(1) Increased intrarenal pressure.

(2) Congestion and edema of the organ under the influence of which it becomes enlarged.

(3) Rapid diminution of the urinary secretion and change in its chemical character; the latter consisting in a marked reduction of its solid constituents.

After the obstruction has existed a few hours, the urinary secretion is almost absolutely suppressed, a few drops only being secreted in the course of each twenty-four hours. Owing to this latter fact, hypernephrosis in a marked degree is seldom seen in connection with complete, continuous obstruction. The enlargement of the organ is almost wholly due to congestion, and the urinary accumulation plays but a secondary part in its production.

(4) When the obstruction has existed for forty-eight hours or so, destructive changes begin in the renal epithelium and in the glomeruli. Once begun, they advance until the obstruction is removed. Their extent is therefore proportionate to the length of time during which the obstruction is present. If the latter lasts long enough, total destruction of the organ results.

(5) If the kidney is infected, the destructive changes take place more rapidly than when it is not infected.

(6) The degree of functional capability that is retained by an obstructed kidney cannot be determined by the thickness or thinness of the cortical substance that is found when operation is performed upon it, for the essential changes upon which the future of the kidney depends are histological in character. Thus there may be in one case a very thin layer of the secreting substance which has not been invaded by the destructive changes to such an extent as to prevent its performing useful service for many years after the renal obstruction has been relieved, while in another instance in which there is a comparatively large amount of the renal parenchyma left, its working capacity may have been practically destroyed by the changes which have taken place in it of a destructive nature.

(7) The only means of estimating the future functional capability of the obstructed kidney is by examination of the urine that comes from it after the re-establishment of the urinary secretion. This, however, cannot be determined from the urine passed *immediately* after the removal of the obstacle, for there are intervals of considerable length — sometimes from four to six months — during which the urine continues to be poor in solid constituents, and yet, at the end of this time, it may show such improvement as to indicate that the organ is doing useful work.

The above is a bare outline of the more important changes that take place in the kidney under these conditions. The essential things to be remembered in connection with them are: The longer the kidney remains obstructed, the greater is the extent of the injury done to it, and correspondingly, the greater is the patient's danger; that the destructive changes in the organ begin within a few hours after the establishment of the obstruction, and that they progress more rapidly when the kidney is infected than when it is not.

Anuria. — It is customary to assert that the anuria seen in connection with these cases does not occur if the kidney of the other side is normal, and that in order to have it produced, one or another of the following conditions must be present concomitantly: (1) Absence of the other kidney, or disease of it sufficiently serious to have destroyed or greatly injured its functional capability. (2) Simultaneous obstruction of the ureters of both kidneys or closure of the single channel made by their fusion, such as is seen in connection with certain renal anomalies.

In other words, that reflex influence is not capable of suppressing the urinary function of the other kidney when the latter is normal or but moderately diseased.

That this is not absolutely the fact is shown by two or three post-mortem observations in which the unobstructed kidney *was* found to be normal or very nearly so. Further evidence in support of the occurrence of reflex suppression under such circumstances is supplied by two clinical observations and by some recent experiments of Götzl.

The former consisted in having found the opposite kidney to all appearance normal, in a case in which it was cut down upon and incised after a primary operation on the other kidney, the second operation having been done because of the persistence of the anuria after the first one, and in another case in having drawn normal urine from the opposite kidney by a ureteral catheter after the re-establishment of the urinary secretion.

In the experimental work of Götzl, he succeeded in producing complete suppression of the urinary secretion of one kidney by increasing the intrarenal pressure in the other, in two of twelve dogs which were used in the experiments.

It is to be noted, however, that similar experiments performed by others have not yielded the same results as those of Götzl.

* Read before The Massachusetts Medical Society, June 7, 1904.

I have dwelt upon this feature of the subject because of its possible importance with relation to the surgical treatment of those cases in which the anuria persists in spite of the relief of the obstructed kidney afforded to it by a nephrotomy. For it suggests that there may be a reasonable chance of re-establishing the urinary secretion in such instances by exposing and incising the other kidney, should the anuria persist for twenty-four hours after the nephrotomy has been done on its fellow, when the former and if the former is normal or but moderately diseased and its function suppressed by reflex influence only. That these conditions are rare is undoubtedly true.

The most striking feature of obstructive anuria is the length of time it may last without giving rise to uremic symptoms and without causing death. These are the characteristics which serve to distinguish it from the anuria which occurs in connection with other conditions.

In order to determine various points in connection with this subject, I have collected and analyzed two hundred cases published by different writers. These cases are derived from the following sources:

Morris (Surgical Diseases of the Kidney and Ureter. 1902).

Schenck (Johns Hopkins Hospital Reports. 1902. Vol. x, p. 447).

Tenney (BOSTON MED. AND SURG. JOUR., Feb. 4, 1904).

In addition to the above are twenty-four cases, as follows:

Loumeau,	2 cases.	(Compte rendu de l'Association Francaise d'Urologie, 1896–97, p. 194.)
Pousson,	1 case	(Ibid., 1898, Vol. 3, p. 370.)
Vignard,	1 "	(Ibid., 1898, Vol. 3, p. 378.)
Albarran,	1 "	(Ibid., 1898, Vol. 3.)
Escat,	1 "	(Ibid., 1898.)
Chevalier,	1 "	(Ibid., 1896–97, p. 485.)
Begouin,	1 "	(Ibid., 1896–97, p. 187.)
Chevalier,	1 "	
Duret,	1 "	
Desnos,	1 "	(Ibid, cited by Begouin.)
Championniere,	1 "	
Bazy,	1 "	
Nicholich,	1 "	(Ibid, 1903–04.)
Cabot,	2 cases	(Annals of Surgery, 1903, October.)
Fairchild,	1 case	
McKay,	1 "	(Montreal Med. Jour., 1903, Vol. 32, p. 641.)
McArthur,	1 "	(Annals of Surgery, 1903, Vol. 37, p. 294.)
Bevan,	2 cases	(Annals of Surgery, April 5, 1903.)
Grohe,	1 case	(Arch. fur klin. Chir., 1902, Vol. 66, p. 178.)
Watson,	2 cases	(Jour. Cutan. and Gen.-Urin. Dis., Vol. 9, and present communications.)

Duration of Anuria. — One hundred and ten cases treated expectantly. Thirty recoveries. Eighty deaths.

In twenty of the cases in which recovery took place the duration of the anuria was as follows:

DAYS	CASES	
1	1	
3	1	
5 to 10	11	(The larger number of these cases had anuria from 5 to 7 days.)
11	1	
13	1	
14	2	
15	1	
15 plus	2	
	20	

The duration of the anuria in 42 fatal cases in which its length is stated was:

DAYS	CASES	
4	1	
5 to 15	25	(The larger number were between 5 and 8 days.)
15	2	
16 or more	14	(23 days was the longest period. There were remissions in a few of these cases.)

Ninety-five cases treated operatively. The duration of the anuria prior to operation was stated in 39 of these cases. Of these, 26 recovered and 13 died. In the 23 cases in which recovery followed operation, duration of anuria was:

DAYS	CASES
1	2
2	2
3	2
4	2
5	2
6	7
7–8–9 (1 each)	3
11	1
12	1
13	2
14–15 (1 each)	2
	26

Fatal cases 13. Duration of the anuria was:

DAYS	CASES
2	2
4–5 (1 each)	2
6–7 (2 ")	4
8–9 (1 ")	2
12	1
4	1
5	1
	13

"*Period of Tolerance.*" — The time after the beginning of the anuria during which the patient remains free from uremic symptoms, is called the "period of tolerance." Its duration was stated in 62 cases. In the larger number of these it was from four to seven days. In 4 it was twenty-four hours or less. In 2 it was two days, and in 14 it was from ten to sixteen days.

To what is to be ascribed the remarkable immunity to uremic intoxication displayed in some of these cases? The most plausible explanation seems to the writer to be that which is afforded by assuming it to be due to the so-called "*internal secretion*" of the kidney.

The theory with regard to this distinctive functional office of the kidney may be expressed briefly thus:

Beside the separation of urea and other excretory products from the blood, with which we know the kidney is concerned, it has another functional duty, namely, that of secreting certain principles of unknown nature, which are returned to the blood through the renal vein, and which have a value in preserving the general nutrition and health of the organism and which,moreover, inhibit in some degree the action of the uremic toxins.

In support of this theory may be cited the experiments of Vitzou recently published. One of a large number of similar ones made by him will serve as an illustration of all of them.

Vitzou removed both kidneys from two dogs, from the renal vein of which he had previously drawn a certain quantity of blood, in such a way as to have it keep sterile. This blood was defibrinated, filtered, and placed in sterile glass jars until it was required.

One of the dogs was allowed to die without interference. The second one was given subcutaneous injections of the blood of the renal vein prepared as above described. The first animal died in thirty-four hours after its kidneys had been removed, presenting characteristic uremic symptoms. The other dog lived for nearly seven days, or 130 hours longer than the one which had not received the injections of blood from the renal vein. Moreover, it was seen that the first appearance of the uremic symptoms could be delayed for a good many hours if the renal vein blood was injected in anticipation of their manifestation, and also that they could be made to cease and their reappearance delayed for a considerable interval if the subcutaneous injections were given as soon as they were manifested and repeated between that time and before the next manifestation occurred. In order that this theory may become applicable to the cases which we are considering, we must assume that the "internal secretion" has not been arrested by the influences which have led to the suppression of the urinary secretion, and that it continues to supply those elements which inhibit the action of the uremic toxins, or which increase the resistance of the organism to them.

Other points which may be noted with regard to the anuria and uremic manifestations are as follows:

If the kidney which is obstructed is already hydronephrotic, the life of the patient and the period of tolerance are prolonged as compared with the cases in which hydronephrosis is not present.

Another feature that should be remembered is, that during the period of tolerance, the patients are frequently to all appearance in good health, and that in some instances death has occurred suddenly without any uremic manifestations whatever, and not long after the beginning of the anuria. I can, however, find no instance in which this has been the case after a period of anuria of twenty-four hours or less.

No one can foresee at what moment uremia may occur, and Morris has well said that in these cases "uremia is always imminent."

Treatment. — In considering the treatment, we may separate the cases into two groups: (1) Those in which the symptoms are not sufficiently characteristic to enable us to recognize the nature of the trouble, or in which it is difficult to determine on which side the obstruction is located, and (2) Those in which the diagnosis can be made with reasonable or entire certainty.

Belonging to the first group are patients who have pain on both sides, or who have had it previously, but who do not have it when seen by the surgeon; or again, such as have pain on one side and tenderness or spasm of the abdominal muscles on the other, etc., etc.

Under these circumstances, if the patient's condition is such as to permit it, the use of the x-ray, the ureteral catheter and the cystoscope may render valuable service. Otherwise, the two latter are both unnecessary and useless in this class of cases.

In cases in which there has been pain on both sides, but in which it no longer exists when the patient is examined, and in which we are obliged to operate without delay, we should choose the side on which the pain was located last.

If we cannot determine which of the two sides is the seat of the trouble, it is better to take the chance of operating on the wrong one than not to operate at all; and if it is found that we have operated on the wrong side we should not hesitate immediately to expose and incise the other kidney.

In the other group of cases, viz., those in which there are *characteristic* symptoms, one or more of the following conditions are presented: Enlargement of the obstructed kidney, tenderness or pain of it; spasm of the abdominal muscles of that side, and, in the cases in which the kidney is infected, probably also chills or rigors, and nausea and vomiting.

Assuming that we have a case in which the diagnosis is reasonably assured, what is the treatment to be?

Apart from the surgical treatment, the following measures are available:

Subcutaneous injections of saline solution, with a view to delaying or mitigating uremic symptoms.

In cases of calculous obstruction, hot hip baths, and manipulation to aid the passage of the stone. The latter has often been successful.

Some surgeons advise the employment of anesthetics for the purpose of relaxing spasm of the ureter. Theoretically this is unsuitable in cases of anuria. Practically it has seemed to be beneficial in some of the cases reported.

When the obstruction is due to a kink of the ureter produced by movable kidney, the patient's hips should be raised, the abdomen relaxed, and the effort made to replace the organ in its normal position.

Operative treatment. — Other than the above methods of treatment, there are two courses that

may be pursued: (1) To treat the case expectantly. (2) To treat it operatively.

The decision as to which of these to adopt is not difficult in any case in which the diagnosis is reasonably clear. The evidence upon which this statement rests is: (1) The knowledge that we have of the changes that occur in the kidney when it is completely obstructed. These have been already detailed in the first part of this paper. (2) The results of clinical experience. The latter is shown by the analysis of the 200 cases which are the basis for some of the conclusions arrived at in the course of this study.

Of the total number of 205, there were 110 patients treated expectantly, and 95 who were subjected to operation.

The mortality of those treated expectantly was 72.7%. That of those treated operatively was 46.3%.

It was also seen that the longer the operation was delayed after the beginning of the anuria, the higher the death-rate became. Again, that a comparatively small number of the patients who had exhibited well marked uremic symptoms recovered under any form of treatment, and that of those who did survive under such circumstances far the larger part were treated operatively.

Further, it was found that there have been a few instances in which patients survived who had profound uremia at the time at which the operations were performed, and who had also had long periods of anuria. Such cases are reported by Chevalier, Duret, and Desnos. They serve to show that we should never refuse to operate even under such unfavorable conditions.

Other determining factors are these: We know that if the obstruction is not relieved, the patient will die in a comparatively short time. We know that death may occur suddenly and soon after the beginning of the anuria without the patient having had uremic symptoms. We know that uremic manifestations may occur at any moment during the anuria, and that once they have appeared, death follows with but few exceptions within three or four days at most.

No one is capable of foreseeing at what time these things may happen. No one can assert that the obstruction will be relieved spontaneously in any given case.

The fact that there have been some cases in which the obstruction has been relieved spontaneously after long periods of anuria and of tolerance, and that recovery has followed, does not justify us in delaying operation because of the hope or the expectation that the same experience will be repeated in any other case.

The conclusion, so far as the choice of treatment is concerned, is inevitable, and it is this: That in every case in which the obstruction has not been relieved by the end of the first forty-eight hours at most, operation should be performed. If uremic symptoms should appear before that time, operation should be done at once.

The delay of forty-eight hours is justified in some cases of calculous anuria, because we know that the destructive changes in the kidney will not have advanced to an important extent before that time; because very few patients have died after periods of anuria of such short duration as that, and finally, because the calculus may pass at any time within that time.

In other words, so long as the kidney is not suffering injury of consequence and there is a fair chance of the obstruction being relieved spontaneously, there is no serious objection to waiting, but at the expiration of this time, delay is no longer permissible. The line which separates the one from the other of these periods may be drawn at the end of the first forty-eight hours, at the furthest, from the beginning of the anuria.

Choice of Operation. — Having decided as to the kind of treatment to be adopted in a general sense, there remains to be considered the choice of the operative method.

In a few cases of calculous anuria the cystoscope has detected the stone projecting from the mouth of the ureter, and it has been removed from within the bladder by the finger or by instrument.

When a calculus is situated close to the lower end of the ureter, it may sometimes be dealt with advantageously from within the bladder also.

Occasionally a calculus is so large that it can be felt through the abdominal wall, and it can be better approached by a more direct route than that offered by lumbar nephrotomy.

The limits of such a communication as the present one do not permit me to enter into the question of locating calculus in the ureter, the relative frequency with which the different parts of the ureter are the seat of calculous impaction, etc. Moreover, these matters have been very fully dealt with by Israel, Tuffier, Morris and others abroad, and in this country by Schenck of Johns Hopkins, and by Dr. Tenney here, in two admirable articles already referred to.

I shall therefore confine myself to the consideration of some of the more general features connected with the choice of operative method.

One broad proposition underlies and applies to the surgical treatment of all these cases. It is this: The essential point by surgical intervention is the re-establishment of the urinary secretion by supplying a free avenue for the escape of the urine from the obstructed kidney by whatever operation will accomplish it most speedily and with the least shock.

There is no question that these requirements are best fulfilled by a quickly performed lumbar nephrotomy.

It goes without saying, that if at the same time the cause of the obstruction can be removed without thereby increasing the severity or prolonging the time of the operation to an important extent, it should be removed. Cases in which this can be done without too much risk, are those in which a calculus is impacted in the renal pelvis or in the upper third of the ureter, from which positions it may be removed usually without too much loss of time. Again, the time lost in

anchoring a movable kidney which has caused a kink of the ureter and its occlusion is usually not of enough consequence to deter us from doing it and thus preventing the recurrence of the trouble.

Of course, it is understood that failure to remove the obstacle at the time of doing the nephrotomy, makes the establishment of a renal fistula much more probable. The evils of even a permanent renal fistula depend in large measure upon the ability to have it properly cared for, the patient's surroundings, his occupation, etc. It is by no means an unmitigated evil when the above factors are favorable.

I have a patient at this moment who has worn a bottle attached to his back for ten years, and for the past year a second one as well. The urine of each kidney has been delivered into these receptacles respectively by tubes which are placed in the renal fistulæ in the two loins.

During the entire time he has been in excellent health; not a drop of urine leaks around the tubes; he soon became accustomed to them and suffers no discomfort whatever from their presence. He has been in active business all the while and no one has been aware that anything was the matter with him. The renal fistulæ have kept this patient not only alive but in perfectly good health all this time. To-day the kidney operated upon one year ago has a percentage of urea of from 1.60 to 1.90. That of the kidney operated upon ten years ago —1.30 to 1.70% of urea. The latter has not varied from the time of the operation, in the sense of diminishing the percentage of urea found to be present.

The safety of the patient lies primarily in relieving the obstructed kidney. His future comfort may be imperilled by failure to remove the obstacle, but his life may depend upon not attempting to do so in the first instance.

The nature of the operations done in the ninety cases was as follows:

	Cases	Deaths	Recoveries	Mortality
Lumbar Nephrotomy,	65	9	56	15.2%
Ureterotomy,	15	3	12	20.0%
Pyelotomy,	5			
Abdominal exploration and passage of calculus by manipulation,	2			
Exposure of kidney and incision of capsule,	3			
	90			

Immediate closure of the nephrotomy incision. — The temptation is strong to close the kidney incision immediately, when we are sure that the obstacle has been removed, and when the organ is not infected. It has been successfully done several times. But it should be remembered that it is the very fact of maintaining the opening in the loin, for a time at least, that allows the kidney to resume its function in whatever degree it is capable of doing. We know that this resumption is not immediate upon the removal of the obstacle, and, finally, it is possible, even in cases in which the obstacle has been removed, that we may invite a repetition of, or aid in maintaining, an abnormal degree of intrarenal pressure by immediate closure of the renal wound. On all these accounts it would seem wiser, therefore, to leave it open. In the instances in which the obstacle has been removed its healing will not be seriously prolonged by so doing.

If it is known that the patient has but one kidney, or that the function of the one which is on the side opposite to that which is obstructed is destroyed, this fact is a reason for operating sooner rather than later.

In this connection may be mentioned some of the cases of this sort which have been published:

Auvray. — Calculous anuria — destruction of the kidney of the other side by obliteration of the ureter. (Bull. et mem. de la Soc. Anat. de Paris. 1899, vol. 74, pp. 597–600.)

Loumeau. — Calculous anuria. Nephrectomy done on the other kidney one year previous. Patient refused operation, and died uremic on the 5th day. (Compte rendu de l'Assoc. Franc. d'Urologie. 1896–97, p. 194.)

McArthur. — Calculus removed from right kidney by nephrolithotomy. Nephrectomy done on same kidney later. Anuria. Nephrotomy upon the remaining kidney. Recovery. (Ann. of Surgery, Phila. 1903, xxxvii, pp. 294–296.)

Nicholich. — Calculous anuria. Nephrotomy on the 15th day. The kidney was tuberculous as well as obstructed. The other one had been removed for tuberculous disease some time before. Recovery followed the second operation. (Assoc. Francaise d'Urologie. 1903–04, vii, pp. 639–642.)

McKay. — Pyonephrosis of left kidney. Nephrectomy. Subsequent calculous anuria from obstruction of remaining kidney. Nephrotomy. Recovery. (Montreal Med. Jour., 1903, xxxii, pp. 641–648.)

Ferguson. — Nephrectomy. Anuria from blocking of other ureter. Nephrotomy, and finally suprapubic cystotomy. Recovery. (Jour. Amer. Med. Assoc., 1903, pp. 8–10.)

Chevalier and Mauclaire. — Anuria of four days in a patient having but one kidney. Nephrotomy. Recovery. (Assoc. Francaise d'Urologie. 1896–97, p. 485.)

Two other cases which have not been published have come within my personal knowledge. In both there was but one kidney. In both, the periods of anuria were comparatively short. They were thirty-eight hours and three days, respectively. Both patients recovered; one under expectant treatment, and one after nephrotomy and the removal of a calculus from the upper end of the ureter. In both cases nephrotomy had been done at some time previously upon the other kidney.

As has been said, speed in the performance of the operation is of the highest importance; often it will have the character of an emergency; and as we know, even such of the patients as do not show evidence of uremia or of being seriously ill, have all of them been accumulating toxic elements, and are not in condition to resist surgical operation well.

Any device, therefore, which will enable us to shorten the time of the operation is a most welcome addition.

I have derived the greatest assistance from the use of the "Kidney Operating Table" devised by Dr. J. H. Cunningham of Boston, in the performance of all lumbar renal operations. It is, I think, far the best means at our disposal for the purpose, and I take pleasure in commending it to your favorable notice. I have asked Dr. Cunningham to demonstrate it here this afternoon, and I will not anticipate what he will have to say about it himself.

BIBLIOGRAPHY.

The following 22 cases are taken from the tables of Schenck and of Tenney, to which references have already been given in the body of the article:

		Cases
Bardenheuer	1882	1
Bergmann	1887	1
Ceci	1897	1
Deaver	1902	1
Ferguson	1903	1
Hind	1894	1
Israel	1888, 1896	4

DISCUSSION.

DR. BENJAMIN TENNEY of Boston said that he had had an opportunity of seeing two types of anuria in the same patient on whom he operated. Some of these attacks before the operation lasted for eighteen hours. Fifteen months after the ureteral calculus was removed, the patient slipped and fell in a sitting position. This was followed by considerable pain on the operated side, and one month later he was called to see the patient who had been working on her feet for several consecutive hours.

On examination a tender swelling the size of a child's head and movable was felt on the left side. Within an hour after lying down with hips elevated the swelling entirely disappeared, and the patient's bladder had been filled and emptied twice.

The earlier attacks were due to the presence of the calculus, and the last to a kink in the ureter, caused by the slipping down of a large kidney. A second operation may be necessary to keep the kidney up in place.

Dr. Tenney agreed with Dr. Watson that anuria was frequently connected with a mechanical obstruction. In all the cases which he has looked up in connection with the article to which Dr. Watson referred, there was evidence of such obstruction.

In the twenty-one cases of anuria which appeared in the combined tables of Dr. Schenck and Dr. Tenney, there was an operative mortality of 52%. Morris speaks of forty-nine cases operated upon with a mortality of 49%, and compares this with the mortality of 80% in cases not operated.

The speaker believes that draining the pelvis of the kidney through the loin added so little to the risk of an already grave condition that it was the only treatment to be considered where the anuria had lasted more than thirty-six hours.

DR. PAUL THORNDIKE of Boston: In the first part of his paper Dr. Watson called our attention to the well-known fact that if the renal outlet is partially occluded for a longer or shorter interval there results a hydronephrosis, while if the obstruction is complete and sudden the renal function practically ceases with equal suddenness and the organ begins to degenerate. If there be an infection as well, the destructive process is so much the more rapid.

Now if the renal function is so interfered with that the unobstructed kidney ceases to functionate (from reflex causes) we get a more or less complete anuria, and if operation upon the obstructed kidney fails to re-establish the renal secretion it is conceivable that a second operation upon the other (unobstructed) kidney might be indicated. This has never come within the range of my experience and I should like to ask Dr. Watson what degree of suppression of urine would indicate the necessity for such an operation and how long he would wait after the first operation before cutting down upon the second kidney?

I wish to add my word of commendation for Dr. Cunningham's table. It has several times enabled me to explore kidneys and remove stones from them without the delivery of the organ on to the loin, and that is something which I have rarely been able to accomplish before.

REMARKS UPON THE GENERAL PRINCIPLES OF MANAGEMENT OF PULMONARY TUBERCULOSIS.*

BY S. G. BONNEY, A.M., M.D., DENVER, COL.

DESPITE the vast interest attaching to the review of the tuberculosis problem, its present status must be regarded as somewhat unique in the diversity of opinion entertained by medical men concerning the rational management of the disease. This appears remarkable in view of the fact that the consensus of opinion among all qualified observers relates solely to the consideration of out-of-door life, rest, superalimentation and a suitable régime, as the all important factors. It is difficult to understand how there can exist such widely differing inter-

* Read before the American Climatological Association, Philadelphia, June 3, 1904.

pretations of the application of these basic principles, as to permit the resulting multiplicity of ideas and divergent methods of practice, where uniformity of thought and action reasonably might be anticipated. Yet there is being promulgated from numerous sources bearing the stamp of authority and conveying perfect honesty of purpose, the endorsement of several distinctive methods of treatment which appear unalterably opposed to each other. These differences pertain to the various constructions placed upon the relative value of the above mentioned essential principles. A more or less partisan appreciation of their comparative merits is developed by the immediate environment and special opportunities of the observers. Thus is to be explained the repudiation in some quarters of the advantages of climatic change for any case, and in others the advocacy of several totally differing localities for nearly all classes and conditions. In like manner is noticed the strenuous insistence by some upon a rigid disciplinary régime within a closed sanatorium, as applicable to all cases of consumption regardless of many vitally important considerations, and at the same time an equally unyielding adherence by others to the alleged superiority of the conditions rendered possible at home. Unfortunately the picture sometimes is painted in its most dismal colors by ardent opponents. The invalid, in the mournful contemplation of banishment to a distant clime, incarceration within the walls of an institution for consumptives, or seclusion upon his back porch, and perhaps in an unsightly yard, often may wonder which fate can possess the least terror.

It does not necessarily follow, that because one of these methods is rational in certain instances, that the others are necessarily inapplicable for other cases. Manifestly each has much of merit according to the individual conditions imposed, and through the exercise of an intelligent discrimination on the part of the medical adviser may be utilized for the material aid of an appropriate class.

Conceding that each case is a law unto itself and must be judged solely upon the intrinsic merits of its many component factors, is it not time that preconception of fixed ideas as to the management of consumption gives way to a just recognition of the valid and established claims of several methods. The application of the various principles of treatment to an individual constitutes a responsible trust, the satisfactory fulfilment of which can be afforded only through a sufficient appreciation of its true character.

It is not the most complete interpretation of a single element no matter how important that is to accomplish the best results, neither is it the most radical conception of several thoroughly accepted principles if at the obvious expense of remaining factors perhaps not so well recognized yet entirely pertinent to the invalid in question. The fullest measure of success in management is to be obtained only by the wisest possible grouping of all the favorable influences pertaining to the case itself. This imposes an obligation towards a painstaking regard for detail, necessitating a vast amount of study as to the special needs and requirements in each instance. This personal effort directed to the critical analysis of all the phases of each case, historical, physical, temperamental, financial, domestic, social, recreative, industrial, etc., is absolutely essential in order to afford not only a wise preliminary guidance, but also to facilitate subsequently the continued adaptation of the consumptive to a proper environment. Thoughtful study and alert vigilance must be maintained throughout the entire period of observation, in order to provide such mode of life and surroundings as are especially appropriate to changing conditions, and in harmony with the varying needs of the patient. This direct personal attention to detail constitutes the first cardinal feature in the management of pulmonary tuberculosis applicable alike to all climates and all methods.

The next consideration relates to the question of climatic change.

There should be no argument concerning the great value of such an influence in the treatment of consumption, provided there is instituted a proper selection of cases and a conjoined attention to mode of life. Desire to exploit the virtues of any particular climate herewith is disclaimed. Such practice as little becomes the medical residents of favorable localities as does the flaunting renunciation of climatic truths those who are pleased to indulge in such vagaries. May it not be asserted, however, that a consistent regard for the very principles upon which depend opposing claims necessarily carries with it an almost incontrovertible argument in favor of climatic change for a large number of cases. If out-of-door life constitutes a desirable feature of treatment at home, why is it not infinitely better when practiced in such localities as permit its more complete fulfilment? If fairly satisfactory results in early cases may be obtained by virtue of certain features of regimen without other beneficial influences, is it not reasonable to expect still better results and among a larger class of cases by means of the same watchful observation with the added opportunities for outdoor air, sunshine, warmth and dryness incident to favorable climates? It would appear that only in such localities could the fullest conception of a proper method of living satisfactorily be conducted.

It must be insisted, however, that there is something in climate distinctly and entirely apart from these factors of sunshine and outdoor air. Reference is made to the influence of altitude in wisely chosen cases, as producing vesicle dilatation, increase of hemoglobin and red blood corpuscles, and improvement in the vigor of the circulation involving digestive and nutritional changes of vast import. Aside from such considerations as the foregoing, may be mentioned the value of the psychic element involved in all changes of residence. This can react for good or evil according to the degree

of intelligence and sagacity displayed by the medical attendant. Admitting a proper selection of cases and a sufficient personal interest and effort on the part of the adviser to provide suitable environment, there may develop factors of no little value in the novelty of new surroundings, change of food, scenery, custom, companionship, the relief from cares and responsibilities of home and all the interest that attaches to a new country with its stir and energy. Can we afford, also, to entirely disregard the fact that certain climates exist where tuberculosis is very rarely indigenous in spite of the existence of some factors that reasonably might have been expected to produce an increase of native cases? Are there not offered to imported cases better opportunities to gain in the midst of these influences which have prevented the development of the disease in others than when exposed to the same conditions that have been conducive to its origin and spread?

This course of remark is not presented as a plea for health resorts, but merely as an appeal for an impartial consideration of the subject in the interests of the invalid alone. The contention simply is made, that while many cases may be expected to do well under proper supervision even if deprived of the advantages of climate, and that others, reference to which has been made in previous papers, are by no means appropriate for climatic change, yet there does remain another class entitled to receive it by virtue of every consideration, including the results of scientific research, of clinical observation and the instincts of humanity. It is hardly necessary at this time to define in detail the character of cases embraced in this class. A somewhat broad and comprehensive grouping of those for whom some climatic change is justly indicated includes,

First: All those with moderate infection who are not prevented from leaving home by financial embarrassment or other equally cogent reasons.

Second: Those in a similar physical condition, though with but a meagre monthly allowance, provided sufficient accurate information is obtained in advance concerning suitable accommodations at an expense within their limits.

Third: Those admittedly dependent upon their own efforts for support, but, nevertheless, with such slight pulmonary involvement as to permit the performance of out-of-door work in some favorable region where employment may be assured.

Fourth: Those with considerably more advanced trouble but favored by a cheerful, sensible temperament, affluence, determination to succeed, an abiding hope with desire for climatic change, a ready compliance with instructions and an apparent, easy adaptation to new surroundings.

That this grouping of cases, subject only to qualification according to modifying individual factors, is reasonably correct, is shown by the substantial facts of experience in favorable localities, where exceedingly remarkable results frequently are obtained in even very advanced cases and among those with most limited resources.

It thus follows that upon the basis of actual results an assuring welcome may be extended to at least some of those no less worthy if less fortunate than their fellows in their equipment and opportunities. It must not be understood, however, that those hopelessly ill or utterly impoverished should be encouraged for a moment to seek climatic change. For these state and municipal sanatoria provision along lines elsewhere suggested, becomes not only obligatory from a moral sense, but, as well, practical and economic.

As regards the large class with moderate infection, who, though much handicapped by lack of means yet not absolutely impecunious, and the associated group of those with very incipient trouble but dependent upon themselves alone, the decision of climatic change is fraught with much responsibility. The question must be reviewed plainly with the patient and family in all its phases according to the individual conditions in force and is hardly subject to generalization. The real solution of the problem for these people consists in the opportunities at their disposal in favorable regions.

The consumptive poor, while equally entitled with those more favored financially to every aid that consistently can be offered, are at the same time necessarily subject to entirely different processes of thought. The interests of such a class are in no wise subserved by sending to a far country to battle against great odds among strangers and amidst perhaps grossly unfavorable surroundings. A recognition of their inherent claims for assistance by virtue of promptings of human interest and a justification for advising a journey to a distant clime is found only by the definite knowledge of the ready facilities for their proper reception within the bounds of their limited resources. Admitting such provision there would be no greater obligation upon society and the profession than to offer reasonable opportunities for such a class to secure a restoration of health and a resumption of earning power.

As regards the cases embraced under the first division, the somewhat sweeping assertion, that all those with moderate infection in the absence of financial or other important reasons should be permitted to enjoy the benefits of climatic change, is based upon the fundamental principle that such patients possess an inviolable right to receive that early unrestricted consideration and advice which an actual experience has demonstrated to be the safest and the most conservative.

"An enormous class who are intensely anxious to avail themselves of every rational opportunity to recover from their disease, appeal to their medical advisers for nothing less than that which offers the greatest and most reasonable assurance of ultimate arrest. Cases such as these, willing to enter the lists engaged in the prolonged struggle, destined so frequently to be a trial to their patience and a test to their endurance, fortitude and bank account, with their own

existence and the happiness of near ones as the issue, surely deserve such preparation and fortunate choice of battle ground as will insure the greatest probability of final success. The obligation of the physician is not fulfilled by advising merely what is admittedly good, but is satisfied only by urging what is actually the very best for the individual case. It is not a question of the advisability or even the probability of securing arrest at home, but whether such an environment of itself is the method most likely to accomplish this result. Should not the physician in assuming to direct the destinies of his well-to-do patients make a practical application of the condition to himself and advise in accordance with the course he would himself pursue under similar circumstances?"[1]

Another consideration pertaining to the management of consumption relates to the question of the closed sanatorium. Its great practical utility in certain carefully selected cases, and its nonadaptability to other equally defined groups, have been discussed at some length in a previous paper. For several distinct classes sanatorium management was described as actually being demanded. For others institutional treatment was thought to remain *sub judice*, and for still another division it appeared to be contra-indicated.

Waiving at this time any consideration of its rationale and scope for the differing classes at home, its peculiar advantages and the great good it has accomplished, it is sufficient for present purposes to consider only its field of usefulness in favorable regions.

Paradoxical as it may appear, the proposition is advanced based upon the results of a practical every-day experience, that residence within a closed sanatorium offers the best possible conditions to be offered in health resorts to a class of cases, and at the same time that a summary recourse to complete institutional régime distinctly is prejudicial to the best interests of others. These differences pertain to such determining individual factors as the financial status, temperamental peculiarities and domestic conditions. Other considerations which justly may obtain are the possible accommodations other than institutional, and the character of the medical counsel to be obtained either within or without the sanatorium. It may be asserted that the special advantages accruing from a properly conducted sanatorium are not altogether inherent to the institution itself. An ample porch accommodation with wise provision for private balconies and perfect heating and ventilation of rooms, all with sunny exposure and a generous tempting cuisine, of transcendent importance though they be, none the less are to be secured in many instances outside of closed sanatoria. Their attainment frequently is most difficult and imposes a serious tax upon the time, energy and perseverance of the medical attendant, yet in most communities the accomplishment of these latter conditions by no means is impossible through the interested personal attention of physicians who are willing to recognize their responsibilities with reference to such details.

There does remain, however, the problem as to the relative degree of success possible to be attained in the maintenance of a system of strict disciplinary régime. Upon this feature depends to a great extent the usefulness of closed sanatoria. Assuredly, there is afforded opportunity for a more absolute and autocratic control than is permitted elsewhere. This continued vigilant supervision is sometimes necessary for the well-being of certain cases, while an equal amount of surveillance not only is quite unfortunate, but even detrimental, to the best interests of others. Furthermore, a perfectly successful supervisory direction depends, either within or without an institution, almost entirely upon the personal influence of the physician himself. As is stated in another paper: "It is almost purely a question of personal equation, and demands a certain aptitude for the peculiar requirements of the position and devotion to the work for its own sake, an interested and solicitous regard for the slightest welfare of the patient, a degree of sympathy, tact and enthusiasm which may almost be said to constitute a form of genius. This may be exercised without an institution as well as within, the sanatorium itself being in most instances a most beneficial accessory to this result rather than as a *sine qua non*. It is the man, not the institution that determines the degree of co-operation and hearty good-fellowship between physician and clientele which alone insures a proper disciplinary régime." By as much as it is not the sanatorium alone but also the attending physician that determines to a degree the influence for good, by the same token must it be remembered that it is not the disease to be solely considered, but the invalid himself.

This presupposes the consideration of other factors than its purely medical or sociologic aspects. For the consumptive the question of success or failure depends frequently upon his ability to adapt himself to unusual conditions, and in this quality he is frequently found deficient. The wisdom of an intelligent modification or adjustment of the immediate environment to satisfy properly the demands of his peculiar requirements is readily apparent. It would seem that the patients for whom such institutions were most particularly appropriate, although by no means exclusively so, were those with such limited finances as to preclude the acquirement of satisfactory conditions without the benevolent aid of partially endowed sanatoria. Were it not for the truly philanthropic agency of such institutions in providing excellent accommodations at a minimum of expense, there could remain for those partaking of its benefit but slight justification for the original climatic change. As regards others, however, experience has taught that the medical adviser, if he so elects, may devote a sufficient supervisory attention to his patients outside an institution, and

[1] "The Sanatorium Treatment of Consumption" by the author.

through the exercise of some painstaking effort may provide accommodations eminently suitable and adapted to their particular needs. There may be instituted proper methods of living in such abodes somewhat along the same lines as in well regulated sanatoria. The same well recognized principles may be enforced, if they desire, upon a smaller scale and sometimes upon a less restricted basis, and frequently more to the actual advantage of the pulmonary invalid. All sanatoria either are or are not conducted solely for incipient cases. In the former case it is hard to see how the favored few with incipient infection and without complications actually can require upon their merits that degree of personal medical attention that necessitates living under the same roof. As regards those sanatoria receiving the average of consumptives as they come, requiring only as a matter of fact such credentials as the stipulated price of admission, it would appear that the social and physical conditions could scarcely be such as would best promote the happiness and contentment of the invalids. Aside from such considerations as these, which surely are more substantial than sentimental, may be mentioned the value of the psychic element to be observed from occasional judicious change of residence and immediate surroundings. This potent influence for good scarcely is obtainable to the same extent under the fullest interpretation of institutional régime.

Let it not be understood that there is implied the slightest reflection upon the very great utility of closed sanatoria even in health resorts. The thought is presented merely in question of their invariable necessity of applicability for all cases.

The views herein expressed are based upon the results of somewhat extended opportunities for observation through the personal management of consumptives in a favorable climate. Fairly accurate records have been preserved in a series of over fifteen hundred private cases that have come under my supervision. The clinical study involved in the effort to recognize essential facts, to analyze experience, summarize the various combinations presented, to apply established principles and to effect a mutual inter-adaptation of individuals to special conditions has resulted, perhaps, in as close personal contact with consumptives and the varying confronting problems that inevitably result, as could have obtained from the more or less routine observation with a corps of assistants in an institution. Those familiar with the nature of such work can readily appreciate the exacting character of the demands necessarily imposed. The conclusions that have gradually assumed shape in the absence of preconceived ideas have been subject only to the molding influence of stubborn facts and a sternly real experience. Statistical deductions are avoided as unnecessary to this inquiry. Such have been included in several previous reports embodying results of clinical observation. As illustrative of methods employed and opportunities afforded, it is not inappropriate to allude in passing to the experience of a recent single year.

During 1902 there were under observation, of whom records were kept, 302 cases. One hundred and thirty-eight of these had lapsed over from preceding years, yet more or less actively under treatment. One hundred and sixty-four were new patients during the year. Of the total number 167 were provided with accommodations to the best of my ability outside of any institution. Seventy-nine resided for varying periods at the Oakes Home for Consumptives without nursing and without hospital facilities other than relate to an excellent location, immaculate cleanliness, scrupulous disinfection of apartments and clothing, ample outdoor facilities, excellent table, sunny rooms, well heated and ventilated. The institution is decidedly unique and without a parallel in its peculiar scope, is open to any practicing physician, and, therefore, without any definite or fixed system of medical régime. There is permitted to any medical attendant, however, the exercise of such supervisory control for his own cases as he sees fit to institute or has the power to maintain. Thirty-nine additional were privileged to occupy rooms in the hospital addition with special facilities to secure outdoor air conjoined with rest by reason of private balconies, and also enjoy the benefits derived from constant skilled nursing. During the last four months of the year there was constructed, through the charity of Mr. Charles L. Adams, an annex to the institution, which provided for the most excellent accommodation of forty people with limited means at a nominal expense. During these four months 25 of my patients resided in this building, each enjoying the advantages of a large private porch opening from the bedroom. None of the above mentioned patients could be said to be contained within the walls of a closed sanatorium proper, yet by virtue of special opportunities and surroundings were permitted to partake of many of its essential advantages with such restrictions concerning mode of life as appeared necessary in individual instances. Of those who resided elsewhere a conscientious effort was made to secure adequate accommodations and to enact a fitting régime according to the varying conditions in force.

The selection of a residence, meeting all known requirements as regards location, sunshine, porch room, frequently outdoor sleeping accommodations, the wise grouping of a chosen few with reference to congeniality, temperamental peculiarities, tastes, stage of the disease and financial ability, the presence of a competent housekeeper, or occasionally a nurse as well, and finally a continuous, if often indirect, medical oversight, has afforded a combination sufficient to produce satisfying results which cannot be here elaborated.

Recourse to occasional change in residence was made from time to time to suit the inclinations and satisfy the apparent needs of those for whom a rational diversion was indicated to

break the unceasing monotony. With the advent of warm weather all for whom a possible justification was found in their condition were urged to avail themselves of the facilities presented for the enjoyment of the benefits of country life and mountain air. Appropriate accommodations at an altitude no higher than Denver were offered at an attractive mountain resort, special arrangements annually being made by me for those whose physical conditions would scarcely warrant sojourn at increased elevations. Thus fifty-two spent the summer at Welch's Resort, near Lyons, upon the banks of one of the finest trout streams in the state. A trained nurse was in constant attendance, more as insurance against accident than because of actual need. Special nurses were employed as necessity demanded.

For the benefit of those for whom a residence in a still higher altitude during the summer months seemed plainly indicated, a careful provision was made, as is my custom each year, at Estes Park, at an altitude of seventy-five hundred feet. All available and properly located cottages were engaged in advance, and finally proportioned among the patients according to the various groupings of the improvised families. Competent persons were employed to assume the responsibilities of housekeeping, and not infrequently trained nurses were retained either by individuals or by several jointly. Nineteen participated in the joys of housekeeping at the Park. For others numbering fifty, comfortable hotel accommodations were retained early in the season.

It is not inappropriate to add that from among the very large number of cases sent to Estes Park during the past six or seven years there has resulted but one hemorrhage and one death, and that in the same individual, resulting from an obvious palpable indiscretion. All patients at these two mountain resorts were seen by me at regular intervals (once a week), with such precautionary advice and admonition as appeared called for by the exigencies of the situation in each instance.

Brief allusion may be made to the conditions which justify sending patients home. This has been advised definitely for all who could be embraced fairly under the category of hopeless cases, unless considered inexpedient for good and sufficient reasons. During the past few years permission to return home for a temporary period at a suitable time of year has been accorded frequently to special cases responding favorably to climatic change, yet not strictly reaching the stage of arrest. A permanent return for those who have secured ultimately an apparent arrest of the tuberculous process is offered upon the basis of the degree of risk and responsibility the patient personally is willing to assume. The invalid is made to realize that in spite of his great improvement a certain element of danger must attend his return. It rarely has been my practice to indorse more than a temporary return save after a six months residence in Colorado following the physical and constitutional evidences of total arrest. It has been my custom to make the consumptive understand, if possible, that once the tubercular infection has become clearly active or extensive, no matter how complete the subsequent arrest, his life necessarily becomes changed in many of its essentials in any climate, and that a continued residence in a favorable region imposes finally less of sacrifice and suffering.

THE GYNECOLOGICAL ASPECT OF MENTAL OVERSTRAIN AT PUBERTY, AND ITS INFLUENCE ON DEVELOPMENT.*

BY WM. EDGAR DARNALL, A.M., M.D., ATLANTIC CITY, N. J.

THE period of puberty is the most critical time in the whole life of the female, because this time of most rapid development of both mind and body may be the starting point for the physical perfection of womanhood or the first beginning of a physical wreck. "Many a young life is battered or forever crippled in the breakers of puberty. If it cross these unharmed and is not dashed to pieces on the rocks of childbirth, it may still ground on the ever recurring shallows of menstruation, and lastly upon the final bar of the menopause, ere protection is found in the unruffled waters of the harbors beyond the reach of sexual storms."

The girl while passing through this period is peculiarly susceptible to mental, moral and physical influences, and during this period may receive the first blow. Ere the girl is fully aware of the change that has taken place, or is warned by her mother of its significance, she has heedlessly exposed herself to injury, and the results may sap her energies through life. It is most important, therefore, that her environment and tendencies should be studied with discreet carefulness.

The average pubescent girl is at school, and under the modern high pressure system of education is straining every nerve to keep up with her duties. Her physical development is slighted, and what vitality she has is all used up in mental effort. It is forgotten that cultivation of the mind and the cramming of the intellect do not comprise the whole of education; and that unless the body is developed along with the mind that more harm than good may be done. The demand for rapid education is the curse of the age. The crowding of children through long years of work often sacrifices health, permanently, for promotion. The work of maturity is demanded by educators, where maturity does not exist.

From the ninth to the sixteenth year is the period of most rapid growth in height and weight, and sexual development begins. From now until the pubertal change is fully established there may be manifestations of physical, emotional and intellectual turmoil characterized by the various neuroses as: hysteria, chorea, epilepsy, somnambulism, neurasthenia, romancing,

* This paper will appear later in the Bulletin of the American Academy of Medicine.

cardiopathies, gastric, hepatic, renal, vesical, genital, metabolic, pulmonary trouble, convulsions, nervous laughs, nervous coughs, anemias, deformities, etc. The neuroses may be of a purely psychic type as: hallucinations, ecstasy, delusions, night terrors, idiocy, imbecility, the various types of insanity, stupor, love, jealousy, anger, hate, theft, rape, arson, homicide, suicide, alcoholism, and the various forms of mental disturbance other than insanity. There may be periodic headache, capricious appetite and muscular twitchings.

During this period the body is developing so fast that brain weight is actually lost by the lessening of the usual blood supply to the brain, which is diverted to nourish rapidly growing organs. The child brain under these circumstances is easily fatigued. What is acquired by a brain that is tired is soon lost, memory becomes impaired, vital force is required faster than it is generated; the work of to-day is done on to-morrow's credit, and the system of the child becomes wholly at a loss to protect itself against disease and accident. "I am convinced," says Pearce, "that from the neurologist's standpoint such children in the cities would do better to have only one session in school, than be compelled to rush to a midday meal, then back again within an hour to recitation, which necessarily requires the freest circulation in the brain to the detriment of digestion, which, of course, is ill carried on under such abnormal circumstances. Over half the general aches and pains, including headaches, are due to disturbance of metabolism from various causes."

The physiologic processes of puberty make greater demands of the girl than they do of the boy, and yet in addition to performing the same work in school as her more rugged brother, her parents are not only anxious that she shall excel in the regular studies, but that she shall also acquire accomplishments, such as music and painting, at an early age. Is it any wonder then that under this system of high pressure and overstimulation the overworked girl, robbed of rest, sleep and exercise, fails to develop physically into perfect womanhood? These years of endless antagonism between brain growth and body growth, years perhaps the most important in her whole life, are very needful for the perfect development of the reproductive organs and the establishment of their functions. On them may hang the whole future health and happiness of the woman and her usefulness as a member of society.

Let me illustrate for a moment what I mean: To-day girls are absolutely started to school before they can dress themselves. They sit in miserably ventilated rooms from six to eight hours with perhaps a few minutes' recess, when they hurriedly eat a cold lunch. At twelve years of age they are studying English, mathematics, and a host of other things. The girl reaches home in the afternoon tired and worn out from efforts that have been too much for her. She must go at once to her music and practice for two hours, or until she becomes so nervous that the notes fail to strike harmony. Supper is announced. Afterward she must begin her preparation for the next day's work, often being forced to study as late as ten or eleven o'clock. Then, of course, her tired brain and body are too exhausted for sleep. This is not an over-drawn picture, and every physician knows that it is not right to subject a girl verging on menstruation, or one in whom nature is making a desperate effort to maintain this function, to such an exhausting strain as this.

Visit the female colleges and you will be impressed with the large numbers of pale-faced girls whose roseate blushes of youth have been chased away by nervous exhaustion born of the shadows of midnight toil; bright eyes have been dulled by brain fag, and sweet temper transformed into irritability, crossness and hysteria, while the womanhood of the land is deteriorating physically and filling our hospitals with invalids, neurasthenics and sexual incompetents. After this weary, worn-out, rest-needing girl is released from school, she launches into the dissipations of society. She may be highly cultured and shine in society, but her future husband will discover too late that he has married a large outfit of headaches, backaches, and spineaches instead of a woman fitted to take up the duties of life.

Accompanying this prolonged strain of school life there is usually a combination of other causes also involved in the school breakdown. Home life is often badly regulated, and the parents or guardians must in many cases share a part of the blame on account of carelessness and unwise indulgences at home. Scant attention is given to the functions of the bowels and bladder. Gross carelessness is the rule. There is an utter disregard in many cases for the menstrual week, when by their own feeling and sensations women ought to know that they are unfit for exhausting brain work or fatiguing body work. The religious systems of Moses and Zoroaster made provision for this period, and even savage Indian women show more wisdom at this period than the product of modern civilization. The tepee of the menstruating Indian is built so low that she is compelled to lie down. Again, the stomachs of girls are often spoiled by an unwholesome diet of sweetmeats, pickles and highly seasoned food, and the bad habit of nibbling between meals. Too long confinement in impure air, inadequate supplies of light, little exercise and poor sanitation complete the evils that other factors have contributed to.

Schmidt-Mounard found in the schools of Leipzig that headaches, sleeplessness and nervous ailments were frequent, especially among girls. Those schools, however, in which attention was given to gymnastics and other forms of exercise had a much smaller proportion of children suffering from these complaints than those in which it was not.

The adolescent period has been termed "the golden period of life when the faculties of both soul and body reach their acme." It is, writes

Alice Smith, "the transitional period when youth begins to look out upon society with the dawning insight of maturity. It is the time when childish illusions are dispelled, and the time when broad, educational influences are most needed." The work should not be such as will overtax either the mental or the physical powers. Girls especially should be exempt from gymnastic work and other heavy physical effort during the menstrual period lest they bring about pelvic disease; and severe mental strains lest they fail to properly develop and functionate. "The gymnastic ideal should be to develop a splendid physique, a sound condition of the body, which means the uniform development of the organism in all its organs and parts." There should be a perfect adjustment of structure to function, a conserving of energy against the strain of future emergencies, and a creation of perfect metabolism, *i. e.*, the balancing of nutrition and waste.

While the inflexibility of school requirements acts as one of the factors in maintaining and perhaps in creating this unhealthful physical state among girls in many instances, yet we are well aware that there are also other and potent causes for it, such as the unsuitable dress of the average female, social excesses, indiscretions in diet, neglect of sleep and the bodily needs which contribute to the result in a large degree. Could the teacher understand the nature and the signs of the extra physical strain to which so large a per cent of the female pupils are periodically subjected, and were she free to temper the demands of the curriculum to meet the condition, much and serious injury might be avoided. Certainly one of the strongest factors in bringing about a reduction of nerve energy and laying the foundation of a future psycho-neurosis is menstrual disorder and an unhealthy condition of the generative organs. The bane of the existence of the schoolgirl worn out from her overwrought and overstimulated life is dysmenorrhea. Chapman thinks that fully 75% who have reached the age of puberty would give a history of scant and painful menstruation. Engelman in a tabulated list of 5,000 cases among schoolgirls found 66% suffering from menstrual troubles. As a result of observations made on 2,000 girls in the schools of New England Jane Kelley Sabine found 75% with menstrual troubles, and 90% with leucorrhea and ovarian neuralgias; 60% had to give up work for one or two days in each month. The fact of the pain being increased with hours of intensity of study, with worry and emotion, and being diminished or ceasing entirely without treatment of any kind during vacation time is a fitting commentary on the underlying causes. These are nervous menstrual pains oftentimes due to a spasmodic action of the uterine muscular tissue. They are augmented by physical exertion and mental strain. The mental or nervous element is a more prominent factor than we usually take it to be, and shows the importance of general management of the girl and the elimination of all injurious conditions of worry and debility, mental or physical, for psychical conditions and nerve influences undoubtedly have much to do with this function.

"Statistics have clearly shown the tremendous susceptibility and the almost feverish activity of the system in the pre-pubertal period, the period of developing womanhood; susceptibility indicated by heightened morbidity and nerve excitement; by increase of stuttering and hysteria; heightened physiological activity by increased growth; and resistance to disease by lowered mortality, — all gradually wane as the vital energies are claimed more and more by the reproductive function, and reach their lowest ebb with the advent of puberty, again rising after menstruation is established, and it is at this period of still unstable equilibrium that we find the schoolgirl."

Similar conditions less intense recur before each menstrual period. Investigation has proven the increased pulse rate, blood tension and temperature, increased nerve excitation and muscular power, with a depression consequent upon the appearance of the flow; the system slowly regaining its normal tension with slight rise shortly after cessation, and these scientific facts are verified and emphasized by the status of young womanhood of to-day, which reflects the present conditions of life and indicates the susceptibility of the physiological function in early years of puberty and during menstruation.

This mental depression is evident in the listlessness, indifference and inability to master tasks easy at other times noted by every observant educator as indicating the presence of the flow and the period of its first advent. It is at this period that overstrain most readily occurs. The powers of attention and concentration are most quickly exhausted and the brightest mind, the most sensitive, high-strung, nervous organization is, as a rule, most responsive and most liable to impairment during the first menstrual periods. The nervous system in the healthy and vigorous frequently shows an excitability which may not pass beyond psychical limits; but in the less strong, often, symptoms which are pathological are developed and the connection between the menstrual epoch and the mental status becomes pronounced. The younger the girl, the nearer the period of puberty, the more impressionable is her nervous system and her susceptibilities for influences good or evil, so that the greatest amount of harm is wrought in the first year of her functional life.

Dr. W. Gill Wylie pointedly expresses the truth when he says that "the American horse receives on the average better treatment than the young woman of America from the time of early girlhood until the age of development has passed. The stock breeder never forces the young animal during the period of development, realizing that it is the time the greatest care should be taken, while American parents, especially of the middle classes, with great ambition for their children and the desire that they develop intellectually beyond their own standard,

allow their heads to be crammed with knowledge so rapidly that the brain cannot assimilate it, and the result is that all the strength of development is devoted to the brain, and the physique finds expansion as best it can. New England furnishes the extreme type of this woman, supposedly more perfect than in any other section, intellectually above the average, but with a physique below par, with greatly reduced reproductive powers, all due to the forcing of study at the age of development."

This forced education, therefore, at or subsequent to the time of puberty leads to flabby muscular development, poorly developed lungs, weak heart and arteries, feeble digestion, anemia, malnutrition of the nervous system, nervous irritation and an increase in neurasthenia, chorea, hysteria and final collapse.

Careful observation will show that a large proportion of the women who make up a neurotic class have arrested development of the sexual organs in varying degrees. The human brain is approximately one forty-fifth of the body weight. It demands about one seventh of the blood to supply its needs. If the education be forced at the developmental period of puberty it needs more to meet the strain. The growing uterus and adnexa must suffer, therefore, in consequence of the withdrawal of blood and the nutrition it should receive. The result is a defect that is very common,—the failure of the uterine cervix to develop. It retains its infantile characteristics. Under these circumstances the uterus is usually abnormally anteflexed, and the canal of the uterus less patulous than normal, with a very small os. The cervix is long and conical in shape and the uterine functions imperfectly discharged. These women nearly always suffer with scant and painful menstruation, while amenorrhoea, menorrhagia and metrorrhagia, endometritis and leucorrhea are common. The entire uterus as well as the tubes and ovaries may be involved in this imperfect development, and may remain more or less rudimentary. Under the strenuous responsibilities of life it is this class of patients who are most likely to break down and suffer from neurasthenia and hysteria, and if of an unstable stock even develop insanity. Much of such lack of development and final breakdown, undoubtedly, has its beginning back in the forcing process of school days, the insufficient attention to physical development, which is allowed to struggle for recognition as best it may, the abuse of the corset and other vicious habits of dress and person.

As preventive measures much can be done by a watchful study of the girl for overwork, by restricting the studies during the establishment of puberty, and if this cannot be done, by taking her from school altogether until menstruation is established. Ambition to excel must be curbed when it is pressing too hard with school duties. Better sacrifice the first place in the class, or fail on an examination than get through at the expense of a poorly developed body, a nervous breakdown, and a dwarfed womanhood.

Especial attention should be paid to a proper regulation of habits at home. All stimulants and excitement, such as late hours, children's parties, and the many artificialities of our so-called modern civilization which tend to bring about a premature maturity should be avoided. Childhood is the time of active development and growth, and as sleep is nature's great upbuilder and restorer, children should have an abundance of it, especially while their vital capacities are being drained by exacting school duties. Especial care must be given to the general health, daily evacuation of the bowels and frequent emptying of the bladder. Proper diet should be looked after, hurried eating and eating between meals absolutely forbidden, knick-knacks and sweetmeats restricted, while plenty of outdoor exercise and healthy recreation should be engaged in.

Even more care is to be employed as the period of puberty advances; that period when the woman's womanhood is struggling with all its energy for recognition, and when the rapid growth of pelvic organs is making exacting demands upon her strength, vitality, and nervous system that must be met. If her supply of vital force is expended in mental pursuits her physique must suffer. Undue excitement, mental worry, or anything that may divert the vital forces from the great work they are performing in the development and perfecting of her womanhood must be jealously guarded from the pubescent girl, for in all her entire life this short period is the most important to her, mentally, morally and physically, and her whole future happiness may hang upon it.

Not until teachers and parents remember that health is more important than knowledge; not until schools realize the futility of the forcing process of education, and guard the health of their girls by diminishing rather than increasing the work of the pubescent period; not until they appreciate more fully that a sound mind depends upon a sound body, can we hope to diminish the pitiable army of suffering neurotics and sexual incompetents, who so largely constitute the womanhood of the land, and who are to be the mothers of the men of our country.

DR. F. B. MALLORY in the chair. DR. L. R. G. CRANDON, secretary.

(Concluded from No. 10, p. 270.)

I. A CASE OF ADDISON'S DISEASE. II. A CASE OF CANCER CONFINED TO THE PAPILLA OF THE COMMON BILE DUCT.

BY GEORGE G. SEARS, M.D.

CASE I. This patient is an engineer, sixty-one years old, who has been in the hospital since Mar. 28. He is an Englishman who claims to follow his family back to the tenth century, so that he has no apparent hereditary right to his very dark complexion. His health has always been good except for an attack of rheumatic fever twelve years ago. He noticed no impairment of his general condition until about three months before entrance when he began to complain of loss of strength. About a month later he bruised his shin, suppuration followed and he was compelled to give up work the following week. He has since felt very weak and drowsy and has been confined to the house. A week before entrance he developed an acute bronchitis.

When first seen there was general pigmentation of the entire skin which extended to the lips. Elsewhere the mucous membranes were normal. The discolorations were more marked in the flexures of the joints, and scattered over the body were numerous areas of deeper color which varied in size from a pea to a ten-cent piece. The pigment is particularly dark in the neighborhood of scars, a number of which are scattered over his body. This is especially well marked about the recent scar on his left shin. Since he came under observation the pigmentation has increased in intensity and has extended to the inner surface of his lips. He is able to be about but complains of great weakness. He has vomited once or twice without apparent cause, but otherwise has had no gastric symptoms. His temperature was at first slightly elevated as a result of his bronchitis, but is now running a normal course. The liver and spleen are slightly enlarged, otherwise physical examination is negative. No tubercle bacilli have been found in the sputum and he has not reacted to 5 mgm. of tuberculin, but there is reason to suspect the activity of our present supply. The urine contains no sugar, but the slightest possible trace of albumen and a few hyaline and fine granular casts have been found. He has been getting one grain of suprarenal extract, at first three times, later four times, a day, without any apparent result one way or the other.

CASE II. The case has considerable interest since the only noteworthy lesion found at autopsy was a cancer, not larger than a pea, which had developed in the papilla of the common bile duct, completely occluding it. It is the only one of the sort which has ever come to autopsy at the hospital. Dr. Mallory tells me that he has seen two similar cases in Dr. A. T. Cabot's practice, in one of which the diagnosis was correctly made by Dr. Cabot before death.

The patient was a German, forty-nine years old, who was admitted to my service on Feb. 27, 1904. His previous history recorded tuberculosis of the knee at the age of sixteen, catarrhal jaundice eighteen years ago, gonorrhea and syphilis. His family history was negative. Five weeks before entrance he had an attack of acute bronchitis. He was given iodide of potash which he says upset his stomach and caused vomiting. Ten days before entrance he noticed that his skin was growing yellow, and about the same time an urticarial eruption appeared, at first on his wrists and ankles, but later over most of his body. The itching became intense. Constipation was troublesome and the stools were clay-colored. Except for jaundice and an eruption of erythema and urticaria, physical examination was negative. The icterus, however, steadily deepened until it assumed a distinct green hue. He slept but little owing to the constant itching, and lost in weight and strength. There arose a suspicion of a fluctuating tumor of indefinite limit below the margin of the liver. Dr. Post, who was kind enough to see him with me, advised against operation on the ground that the trouble was probably malignant. The previous excellent health of the patient, the mode of onset, the coincidence of urticaria and the failure to detect any important evidence in corroboration in physical examination made me hesitate to accept such a diagnosis unreservedly. I was more inclined to attribute the obstruction to a gallstone or to some obstruction outside the duct, *e. g.*, a constricting band. At all events, I thought he ought to have the benefit of the doubt, and on my insistence he was transferred to Dr. Post's service and the abdomen opened by Dr. Paul Thorndike. The operation disclosed nothing abnormal except a distended gall bladder full of viscid bile. The patient died two days later. Dr. Post was vindicated.

I. LEUCOPLAKIA OF TONGUE. II. CICATRICIAL STRICTURE OF PHARYNGEAL ORIFICE, RELIEVED BY PLASTIC OPERATION.

BY G. A. LELAND, M.D.

CASE I. Mr. D., about sixty-eight years old, has been an inveterate smoker and also a copious drinker all his life. About ten years ago noticed some white spots on the tongue, without any pain or discomfort. Four years ago there appeared on the right side of the lower lip near the center a superficial ulceration called a "smoker's cancer" by his physician. He was given a paste or salve for it which healed it, and left no scar. The white patches continued and about a year ago on the under surface of the front of the tongue there appeared a very white thick layer. This has continued since and now has the appearance as if 95% carbolic acid had been painted over the under side of the tongue, considerably elevated, rather hard (horny) to the touch, as far back as the flexure of the floor of the mouth and slightly extending upon it.

On the upper surface are several more or less rectangular patches of a dull white; also on the inside of the lips. About four weeks ago this appearance, especially on the lips, was much more marked, with here and there a slight solution of continuity, with more or less slightly painful irritability. The patient was given 2% solution of resorcin with which frequently to paint the lips, and now they are quite smooth, although here and there having a small white spot. He has no pain nor discomfort, and no curtailment of movement, though pepper, hot drinks, alcohol and tobacco smoke cause the tongue, which is rather large and flabby, to smart. He is now a total abstainer.

This is evidently a case of leucoplakia with extreme proliferation of the epithelium on the under surface of the tongue where it is least

rubbed. It is very much like a case in Mikulicz and Michelson's atlas. This they have named epithelioma, to which end this patient is doubtless going.

CASE II. The next patient, P. H., age about thirty-five, before four years ago had a very extensive ulceration of the skin of the face, the scars of which you see. That of the fauces and buccal pharynx was perhaps even more extensive. As a result of the process of healing both the velum palati and the tongue became firmly adhered to the posterior wall of the pharynx. The glosso-pharyngeal adhesion approached the middle from the sides. This was in the spring four years ago. During March and part of April he came to the throat Out-Patient Department for relief. Dilatation was practised, but the cicatrix contracted more and more till in April he was admitted to the surgical house service. Here certain treatment was instituted which gave him some relief, and he went out, to be again admitted in May. By this time it was impossible for him to get enough air for respiration and tracheotomy was done.

For some time before this it was with the greatest difficulty that sufficient nourishment could be swallowed, and nutrient enemata were resorted to,—about April, 1900, as my memory serves me. After a few weeks he was dismissed from the hospital with the tracheotomy tube in *situ*. In October, he visited the Aural Out-Patient Department and the condition then was, that the only entrance to the esophagus from above the tongue was about sufficient to admit a small surgical probe. The glosso-pharyngeal adhesion seemed to be about ½ inch in thickness. The velum palati was adhered completely, the only opening being about 1 cm. wide by 1½ cm. long near the hard palate.

For the relief of this the method devised by the late Dr. J. E. H. Nichols of New York, a member of the American Larynx Association, was used to produce a cicatricial perforation at the outside limit of the desired division of the cicatricial adhesion, and hence under cocaine a suture was passed down through the remaining orifice and as much of the cicatricial mass was grasped as possible, bringing it out near the right lateral wall of the pharynx. The tissue being exceedingly hard several needles were broken in the attempt, but finally about 3 cm. were enclosed in a very heavy double silk suture. The right side was only attempted at this time. Up to the middle of November or first of December the suture had to be renewed once or twice; but at that time it had cut through so as to leave space large enough to admit an index finger. He was now able to swallow a pretty good bolus of meat well chewed, and liquids and semi-solids without trouble. There was sufficient room for respiration and the tracheotomy tube was removed, the wound healing very satisfactorily; and by the first of the year 1901 he was dismissed. Having had experiences enough of a surgical nature he decided to wait, and did not appear again till a month ago when he thought he would like to have a little more space, that formerly obtained not having contracted perceptibly, but desiring to eat more and faster. With a double curved aneurism needle again under cocaine, a grasp was taken on the left side out as far as possible toward the side of the throat, and the case is now shown so that this suture can be seen in place. It is, as before, a very heavy silk suture doubled, and has already made a pretty good cicatricial opening. It will now be best probably to hasten the cutting through of the enclosed mass by an elastic ligature.

The salient point about this case is that dilatation of such cicatrices around orifices is of no permanent benefit, besides being too slow and tedious; and an interesting point and of some therapeutic value is that he was able to nourish himself for about seven months per rectum.

Medical Progress.

PROGRESS IN THORACIC DISEASE.

BY JOHN W. BARTOL, M.D., BOSTON.

"TAPOTAGE" IN DIAGNOSIS OF CAVITIES.

ERNI[1] claims that such cavities as occur superficially at the apex, *i. e.*, in infra-clavicular or supra-scapular regions, give conclusive evidence of their existence in response to a new maneuver in examination. Taking between thumb and forefinger the tip of a flexible bladed paper knife, weighing perhaps 100 gms., he taps gently on the chest in the suspected area; as he approaches the zone of reaction the patient complains of feeling a movement within, and when over the cavity, at each blow there results a short attack of coughing and immediate expectoration of sputum, evidently representing the contents of the cavity. A possible therapeutic value is also given to the procedure in that, after repeated percussion, the sputum at first purulent becomes mucous and finally disappears, giving the cavity a possible chance of cleansing itself and eventually cicatrizing.

DIAGNOSIS OF ASTHMA BY TRACHEAL TRACTION TEST.

Abrams[2] adds another novelty to his already imposing list of diagnostic maneuvers. In health and in all other conditions so far studied, the tracheal traction test is positive, *i. e.*, when percussion is performed over the manubrium sterni, first with the chin approximating the sternum, and then with the neck forcibly extended, a change in the note is observed from resonant or hyper-resonant to dull or even flat. This change does not take place in spasmodic bronchial asthma, either during an attack or in the interparoxysmal period, but is observed in cardiac or uræmic asthma. The explanation, which, if correct, is in support of the muscular theory as against the angioparetic theory of spasmodic asthma, is that in asthma the tone of the bronchial muscle is so reduced that it no longer reacts in the ordinary way by contracting in response to the stimulation of the vagi, brought about when the neck is forcibly extended on the sternum.

LATENT FOCI OF TUBERCULOSIS. TUBERCULIN DIAGNOSIS.

Cornet[3] emphasizes the misleading nature of statistics based on autopsy findings, where the smallest healed lesions put the individual in the tubercular list, without discrimination as to the obvious virulence or non-virulence of the infection, and founded almost entirely on tabulation

[1] Sem. Med., Mar. 9, 1904.
[2] N. Y. Med. News, June 25, 1904.
[3] Berl. Klin. Wchn., xli, 14, 15.

of cases studied in large hospitals, the inmates of which obviously do not furnish a reasonable criterion of the total population. The relative virulence of different races of tubercle bacilli, and the possibility of lesions histologically indistinguishable being caused by different members of the acid-fast group, of low order of virulence, are both questions which need much further study before we can ascribe as much importance as is commonly given to "power of resistance" or "hereditary predisposition" in explaining lesions that in one individual show evidence of prompt healing and in another rapid advance. Against the positive tuberculin reaction as diagnostic proof or conclusive indication for antitubercular treatment, it is to be logically urged that it gives us no indication of the extent, histological progress or virulence of the assumed infection, and must remain simply a valuable confirmatory evidence when other signs point to tuberculosis.

Hope of clearing up in the immediate future some of these obscure points, however, is suggested by the results reported by Kapralik and v. Schrötter.[4] They have followed up preliminary studies instituted by Cornet himself in 1900 on the action of tuberculin taken by inhalation mixed with water in a finely divided spray. In the first place, it seems proven that, making allowance for the difference in dosage, the signs of positive reaction will be the same whether tuberculin is given subcutaneously or by inhalation. Upon the difference in dosage, and on the varying relation which the injection dose bears to the inhalation dose at different periods in progress of the disease, depend the conclusions in applying the test as a differential diagnostic. Thus in Group I, which includes cases in which the physical signs are obvious, the inhalation dose required to produce a positive reaction averages twenty times as large as the injection dose; while in Group II, comprising those cases in which signs of pulmonary involvement are lacking or absent, the inhalation dose averages 250 times as large as the injection dose. Incidentally, it is assumed that the marked variation in the relation of one dose to the other which may be exhibited by cases in series of Group I, is due to particular characteristics of the individual case, *i. e.*, size of foci, age, activity and varying virulence, while the much more constant relation exhibited by cases in Group II is due to the fact that here the tuberculin of the inhalation does not meet directly with lung tissue that is involved, but simply reacts through the circulation on more remote foci. In conclusion, and as result of study of twenty-eight cases, they strongly advise a combination of the two tests, claiming that while a positive reaction from injection alone shows simply that there is somewhere a focus which only by inference can be fixed in the lung, a positive reaction from the inhalation also will give important testimony based on the relation which the doses bear to one another, as to the actual involvement of the lung and its extent; and further, that a changing relation of the doses as time goes on may lead to important prognostic conclusions, as in cases of suspected infection only, or in conditions tending to change a case from Group I to Group II, or *vice versa*.

JUGULAR THROMBOSIS IN PULMONARY TUBERCULOSIS.

Aldrich[5] reports ten cases (nine from the literature and one of his own), in which, in the later stages of phthisis, there was a quite extensive thrombosis of the internal or external jugular, often extending into the subclavian and farther. He is of the opinion that such a condition obtains much more frequently than is generally supposed, and that even in the early stages of the disease, it is not so rare as might be assumed. As factors likely to contribute to the process of thrombosis, there exist in the advanced cases: (1) Change in the blood; the presence of some bacteria and the toxins of many more, and in terminal conditions a general invasion with the more or less virulent micro-organisms of a mixed infection; (2) changes in the venous wall due to nutritional alterations, as a result of which it becomes a ready lodging place for multiplying organisms; (3) foreign matter in the blood stream tends to formation of fibrin ferments favoring coagulation; (4) with diminishing vital force the influence of stasis is added. Reasons for the frequent location of the thrombi in the jugulars are anatomical, *i. e.*, the existence of the valves and the ease with which an eddying motion of the blood may be set up there.

MUSCLE DEGENERATION AS A SEQUENCE TO INFECTIOUS PROCESS IN LUNGS OR PLEURA.

Coplin[6] presents a preliminary study of changes taking place in the intercostal muscles and the diaphragm as a result of inflammation in lung or pleura. The first step he considers to be a granular degeneration, identical with the cloudy swelling seen in other muscles as a result of infectious process, and probably due to toxins circulating in the blood. Following this, however, he describes changes incident to the involvement of and extension from the adjacent serosa, proceeding in some cases to leucocytic invasion and necrosis, with the ready identification of organisms that in the pneumonias and epipneumonic pleurisies are doubtless pneumococci. The clinical application of these findings is suggested in the likelihood that there well might be modifications in the physical signs as a result of the increased density of the thoracic walls, while the structural changes in the muscles may also play their part in the altered shape of thorax and diminished respiratory function. They also have a bearing on the frequent association of intercostal rheumatism or neuralgia with pneumonia, and the occurrence of pleuritic pains, although the immediate cause of the painful manifestations is probably an implication of the nerve fibres in the degeneration.

PERICARDIAL EFFUSION.

It is apparent that, although effusions of noteworthy size are not difficult of demonstration, their presence is still often overlooked, and that even after diagnosis is made, paracentesis is not unlikely to prove unsuccessful. Thayer [7] reports two cases, both tuberculous, and both with classical signs of large effusion; in one 1,250 cc. of almost clear straw-colored fluid were readily withdrawn by aspiration in the fifth left space, about two fingers' breadth inside the mammillary line; in the other, aspiration in the sixth left space at the sternal border and in the left costo-xyphoid angle was unsuccessful, while at autopsy the enlarged and dilated heart was contiguous with but not adherent to the anterior wall of the pericardial sac, and there was over 1,200 cc. of fluid lying posteriorly and at the lateral angles. So far as these cases go, they lead to the conclusion that the procedure of Delorme and Mignon, which was practiced in the second case, is not a reliable one, but that on the whole the recommendations of Shapojshnikof lead to the surest results. He advises in all cases exploratory puncture with a hypodermic needle, which serves to determine the character of the fluid and often gives important aid in fixing the position of the heart, which as a rule will be found close to the anterior wall of the pericardium, and does not fall downward and backward. In the fourth or fifth left space one is particularly apt to injure the heart, and in cases where the effusion is not large, the third or fourth right space close to the sternum is advocated, providing always that there be dullness at that point. In larger effusions, with diaphragm depressed and the semilunar space occupied by flatness, the sixth left space just beyond the supposed position of the apex is indicated.

Further articles bearing on the diagnosis and relative frequency of tubercular pericarditis are those by Stockton [8] and Seagliosi.[9]

A TEST OF THE HEART'S FUNCTION.

Katzenstein [10] describes at length a new and seemingly very practical method of informing oneself about the power of endurance of any individual's heart, supplying a need that every clinical observer, whether physician or surgeon, feels when the time comes to express an opinion as to the probable effect on the cardiac muscle of an increased amount of work. He was originally led to further investigations by the result of experiments on animals, which showed that ligature of larger arteries called forth in the heart an increase in force, manifested by an elevation in the blood pressure with unchanged or lowered pulse rate; these modifications continuing throughout the period of formation of the collateral circulation, and gradually returning to normal again as the resistance becomes less.

Applying this same principle to the study of the human heart, he found that a marked resistance, even if transiently exerted, would be met by the normal heart with a prompt increase in force without a rise in pulse rate, whereas a heart, insufficient for one reason or another, would change in pressure or rate, or both. The technic consists simply in compressing to obliteration of wave both iliac arteries at the inguinal ligament, and noting what change takes place in the general blood pressure and the pulse rate. Duration of compression is at most five minutes, and does not require great amount of force. As a result of numerous investigations, he tabulates the following standards:

1. In the normal heart an increase of pressure of from 5–15 mm. Hg., while the rate remains the same or possibly becomes slower.

2. In a heart that is hypertrophied and of undiminished force, the pressure rises AT LEAST 15 mm. and may reach 40 mm., while the pulse again is unchanged or slower.

3. In a heart whose muscle is somewhat insufficient, the pressure fails to rise and the pulse is unchanged or faster.

4. In a seriously impaired heart the pressure is lowered and the pulse rate increased. For ordinary purposes it is safe to conclude that if the pulse goes up the heart is unsufficient; if it remains unchanged or lowered the heart has normal force.

In nervous and easily excited patients the precaution should be taken of accustoming them to the manuever for several days before the observations are recorded.

Reports of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

ANNUAL MEETING AT ATLANTIC CITY, NEW JERSEY, JUNE 2, 3 AND 4, 1904.

(Concluded from No. 10, p. 274.)

FIRST DAY — (Continued).

FOUR CASES OF FOREIGN BODIES IN A BRONCHUS.

DR. A. COOLIDGE, JR., of Boston, Mass., presented reports of four cases, three treated by means of a preliminary tracheotomy, and one by Killian's bronchoscope, through the natural passages. In the first three cases, after tracheotomy, a short tube was inserted through the tracheal wound, and the foreign body easily removed through the tube. In three cases a general anesthetic was used; in one, only cocaine spray in the trachea.

The author referred to the change in the attitude of many surgeons toward operating for foreign bodies in a bronchus, since the introduction of direct bronchoscopy by Killian, in that formerly many advised delay or non-interference, whereas now he felt that there was, and should be, little or no hesitation in operating on these cases.

The discussion of these two papers brought out reports of many cases of foreign bodies in both esophagus and bronchi, and many successful removals, but no other cases in which the Killian method and instruments had been used.

PRESENT METHODS FOR THE TREATMENT OF MALIGNANT DISEASE OF THE LARYNX.

Dr. D. Bryson Delevan of New York read this paper. Stating that there was nothing new to present in regard to etiology and pathology, he proceeded to discuss the treatment under the following heads: (a) Internal medication; (b) antitoxins; (c) liquid air; (d) ligation of the carotids; (e) the x-ray; (f) the ultra violet ray; (g) radium; (h) surgical methods. The author dismissed internal medication, antitoxins, liquid air and ligation of the carotids as useless.

The various "radiants" up to date had not proved curative, although enough good has seemed to follow their use in some cases to warrant further and patient work with them.

In general he felt that, from a review of all the various methods of treatment, the radiants, particularly the x-rays, are the best means at our command for the temporary relief of the chief symptoms of advanced cases of laryngeal cancer, and that direct surgery presents the only *certainty* of success in the curative treatment.

The author reviewed the literature of the surgery of the larynx, especially commending the work of Butlin. He recommended thyrotomy and partial extirpation for the cases seen early, with small and sharply limited lesion, and total extirpation for the more advanced cases; and thought that, notwithstanding some disadvantages, a preliminary tracheotomy, some time previous to the main operation, was advisable.

He urged particularly the early recognition of the cases, and also the necessity of having especially skilled and experienced operators and nurses in charge of all thyrotomy and tracheotomy cases, and also laid great stress upon the danger of excising portions of malignant growths for microscopical examination, on account of the irritation and immediate stimulation of the growth to a rapid and extensive development.

THE EFFECT OF TOBACCO UPON THE THROAT.

Dr. Samuel W. Langmaid of Boston presented this paper, giving as his thesis the statement that "smoking is responsible for certain forms of throat disease, or is an added factor in the injurious effects of climate." The author believed that comparatively little nicotine was absorbed, but that most of the poisonous symptoms were produced by the absorption of carbon monoxide gas, possibly by some of the other by-products of the imperfect combustion of tobacco. The author's summing up statement was that "tobacco smoking is not only harmful to the throat as a direct local irritant, but that it produces vasomotor disturbances of the pharyngeal mucous membrane by its poisonous effects upon the nervous system," and that in most cases of acute pharyngitis and nasopharyngitis and cough, due to irritation of pharynx, larynx, or trachea, occurring in smokers, little or no result could be obtained from treatment until or unless the smoking was stopped or much lessened.

FINAL HISTORY OF A SUPPOSED CASE OF VOCAL NODULE; EPITHELIOMA OF THE LARYNX; THYROTOMY; DEATH.

Dr. Charles H. Knight of New York presented this report of a case reported in detail at the meeting in 1901.

With not much change in the nodule, the case was examined during 1902 by several laryngologists, one of whom removed a fragment with a cold wire snare, the microscopical report upon which was "Papilloma of Larynx — Malignant Tendencies." Then followed great reaction, which did not subside, and finally, in December, 1902, a thyrotomy was done, and extensive infiltration found. A few hours after the operation the patient suddenly sat up in bed, gasped for breath, became cyanotic and died shortly afterwards.

The author called attention particularly to the marked stimulation to activity after the irritation caused by removing the small specimen for examination; to the question of the relation between microscopic reports and clinical history; to the question of the possibility of the transformation of a benign growth to one of malignant character, or the development of latent malignancy, and to the fact that we "are still in the dark as to positive signs by which to identify malignancy in its inception."

TWO CASES OF PEMPHIGUS OF THE MOUTH.

Dr. John W. Farlow of Boston read the above paper, calling attention to the rarity of the disease, quoting freely from its literature. Accepting the definitions commonly given of the disease, the author described in detail two cases in which the typical lesions were well marked in the mouth. The blisters occurring on the mucous membranes were so short lived that it was difficult to demonstrate them before they collapsed, and then showed only the slightly raised swellings, with raw surfaces, sometimes reddish in color, sometimes white from the macerated and loose mucous membrane of the collapsed blister. He discussed in full the two main classes of cases, viz.: those in which the eruption occurs on skin and mucous membrane at the same time; and second, those in which the eruption is confined to the mucous membranes alone, either of the mouth, nose, pharynx, larynx and conjunctiva, or any two or more of them. He noted its essentially chronic character, with poor prognosis as to cure, but comparative rarity of death.

As to treatment, he recommended principally care of the general health, and great care of the mouth and nose in the way of cleansing washes, with arsenic for internal medication.

PRIMARY ULCERATION OF THE TONSIL, TOGETHER WITH SOME REMARKS ON TONSILLAR ULCERATION IN GENERAL.

Dr. Thomas J. Harris of New York presented this paper, basing his discussion on the following classes of primary ulceration:

(1) Membranes — ulcerative tonsillitis — the so-called angina of Vincent.
(2) Acute lacunar ulcerative tonsillitis.
(3) Pseudo-diphtheritic ulceration.
(4) Gangrene of the tonsil.
(5) Syphilis.
(6) Tuberculosis.

He described the various clinical forms found under these heads, with the bacteriological findings; and the symptoms. He called attention also to the *secondary* ulceration so frequently found on the tonsil, due to diphtheria, typhoid, tuberculosis, lupus, syphilis (both primary, secondary and tertiary), and malignant disease, and the differential diagnosis between those and the primary ulcerations. In conclusion the author summed up by noting:

(1) The value of bacteriological examination.
(2) The occurrence of the primary ulcerations, which may be mistaken for the graver secondary forms due, *e. g.*, to diphtheria or syphilis.
(3) The almost irreparable harm which may result to the patient from a false diagnosis of syphilis.

BONE AND CARTILAGE IN THE TONSIL.

Dr. James E. Newcomb of New York presented a paper with this title. His attention had been called to the condition by the reports of a few cases pre-

viously published, and two years ago he had seen one case in his own practice.

In removing a tonsil in a woman about thirty years of age, a hard body was cut through, and examination of the tonsil showed that the body was the tip of the styloid process of that side. The other side of the same patient showed nothing abnormal.

Such cases were, perhaps, of greater interest than importance, yet irritation might result if sufficient soft tissue did not pad the stump left in the tonsil. His own patient had suffered no inconvenience, though the stump was easily perceptible on palpation. He spoke of the two theories as to origin of these bony and cartilaginous deposits in the tonsil; one, that they were vestigial rests of the second bronchial arch; the other, that they were due to a metamorphosis of connective tissue. He presented a summary of the comments on these two views by various writers, with brief reports of published cases.

LUPUS OF THE PHARYNX AND NASO-PHARYNX TREATED BY X-RAYS.

DR. HERBERT S. BIRKETT of Montreal read a paper with this title, reporting in full this history of one case, as cured by use of the x-rays. The patient was a boy of fifteen years of age; he had occupied a room in which a brother had died of tuberculosis; he had enlarged lymph nodes in the neck. He complained only of difficult nasal respiration. Was robust and healthy in general appearance.

The lesions were two distinct masses on lateral and posterior walls of the pharynx, extending to vault of naso-pharynx, with considerable surrounding infiltration, but not involving the pillars of the fauces nor the tonsils, and not extending into the posterior nares.

The bulk of the growths was removed by forceps, the surface curetted and rubbed with lactic acid, and as after some time the lesion did not heal, it was then treated with the Röntgen rays. The author then detailed the technique of the x-ray treatment, extending from April, 1903, to July, 1903, "when the local condition in the throat had entirely disappeared." A small area of the same disease appeared in February, 1904, on the anterior part of the cartilaginous septum, which the author claimed to be a *new* area, and not an extension of the lesion from the old infected part. This is now under treatment and yielding rapidly to the same measures used in treating the former site of invasion.

The following papers were read by title:

SUB-MUCOUS OPERATIONS ON THE NASAL SEPTUM; NO PERFORATION — THE END IN VIEW; REPORT OF CASES.

By DR. ROBERT C. MILES, New York.

BRONCHOLITHS, WITH REPORT OF CASES.

DR. D. BRADEN KYLE of Philadelphia presented this paper, speaking of the comparative rarity of the cases, and the fact that diagnosis was seldom made until the concretion was expectorated, and that many stones were found post-mortem, having caused no symptoms during the life of the patient. The majority of cases, however, show symptoms often attributed to tuberculosis, asthma, chronic bronchitis, infection, etc., those symptoms being usually cough, generally paroxysmal, expectoration, pain and general uneasiness, dyspnea, and occasionally hemoptysis. The only pathognomonic symptom is, of course, the expulsion of one or more stones. The author detailed various theories as to the origin and formation of the stones, observed that while they have probably been observed most frequently in tuberculous subjects, they do occur in the non-tuberculous, who after expulsion of the stone become entirely well and remain free from any pulmonary or bronchial irritation, and gave a history of a case demonstrating the last statement.

SUB-GLOTTIC TUBERCULAR LESIONS OF THE LARYNX.

DR. T. A. DEBLOIS of Boston presented this paper, giving the histories of two similar cases in which a tubercular lesion, when first seen apparently an abscess, and later a distinct ulcer, was present on the anterior wall, about one inch below the cords.

These cases both occurred in patients already well advanced in pulmonary tuberculosis, and the laryngeal involvement was undoubtedly secondary to the pulmonary lesion. Both cases resulted in death.

At the executive session of the meeting, the following gentlemen were elected as members: To corresponding fellowship, Prof. B. Fraenkel, Berlin; to active fellowship, Dr. T. Passmore Berens, New York City, Dr. John M. Ingersoll, Cleveland, O., Dr. Harris P. Mosher, Boston, Mass.

The following officers were elected for the ensuing year: President, Dr. Clarence C. Rice, New York; first vice-president, Dr. Thomas Hubbard, Toledo, O.; second vice-president, Dr. Walter J. Freeman, Philadelphia; secretary and treasurer, Dr. James E. Newcomb, New York; librarian, Dr. J. H. Bryan, Washington, D. C.; members of council, Dr. D. Bryson Delevan, New York, to serve for three years, Dr. J. H. Hartman, Baltimore, Md., to serve for four years.

The date and place for the next meeting was left to the decision of the council.

An amendment to the constitution was adopted, increasing the active fellowship from 75 to 100.

Recent Literature.

The Practice of Medicine. A Text Book for Practitioners and Students with Special Reference to Diagnosis and Treatment. By JAMES TYSON, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University; Physician to the Pennsylvania Hospital, etc. Third edition thoroughly revised and in parts rewritten. With 134 illustrations, including colored plates. Philadelphia: P. Blakiston's Son & Co. 1903.

The first edition of Dr. Tyson's "Practice of Medicine" appeared in 1896. This edition, the third, retains the original good features and has been brought up to date, incorporating the changes in theory and practice of the last few years. The chapters on infectious diseases are those in which the most numerous changes occur, but there has been a careful revision by Dr. W. G. Spiller of the section on nervous diseases and by Dr. Simon Flexner of dysentery. The entire book has been reset.

Consumption a Curable and Preventable Disease. By Lawrence F. Flick, M.D. David McKay, Publisher. Philadelphia.

The name of the author who has done such great work in the crusade against tuberculosis would ensure the earnest attention of readers to anything appearing from his pen.

The present work is written for the general public, and is written in a popular manner and contains much that will be of interest and practical value to the public at large. If the style is to the critic somewhat redundant and rather more figurative than seems necessary or wise, that fact may be lost sight of in the recognition of the undoubted merits of the book.

A few of his statements, however, will doubtless be challenged and we believe with justice, especially when, at the end of Chapter XXXVI, he makes the very sweeping assertion that "climate in itself is of little value in the treatment of consumption," that "it is the outside air which counts" and that "it *makes very little difference where this outside air* is gotten from, so it is gotten every day and all the day and night."

That his teachings stand for as fresh air as possible, wherever the patient may be every hour of the twenty-four, is highly to be commended, but that it should be claimed that the vitiated air of cities can be compared with the pure air of the country as an efficient remedy for tuberculosis strikes us as most extravagant and unwarranted and liable to mislead. His Chapter XXIV entitled, "Should Consumptives Marry?" impresses us also as claiming altogether too much in his statement that "immunity gradually comes to those in whose ancestry the disease has existed." While there are doubtless thousands of people apparently free from tubercular taint whose ancestors have been tuberculous, it seems to us that we are hardly justified in drawing the conclusions he makes upon such grounds. Such sentences, too, as "Many a young consumptive mother gets her shroud shortly after she has purchased the christening frock for her babe," and again, "Many a young man has sacrificed his chances of recovery on the altar of Hymen," while containing wholesome truths, strike us as lacking the simplicity of statement which is the most convincing form of argument.

Apart from these blemishes, as they seem to the critic, the book will do good and deserves a wide reading.

La Separation de l'Urine des Deux Reins. Par Georges Luys, Assistant du Service des Voies Urinaires à l'Hôpital Lariboisiere. Préface par Henri Hartmann, Professeur Agrégé à la Faculté, Chirurgien de l'Hôpital Lariboisiere. Avec 55 figures dans le texte. Paris: Masson et Cie., Editeurs, Libraires de l'Academie de Médecine, 120 Boulevard Saint-Germain. 1904.

This small book of about three hundred pages is most attractive to one at all interested in the urinary organs, and it is especially instructive to one wishing to know the evolution of the mechanical appliances for obtaining the urines from each kidney separately. Luys has perfected a very simple device for the separation of the urines. He finds that the apparatus is of very great practical value. Prof. Henri Hartmann, as well as Luys himself, has operated many times, assisted by the evidence which the use of this instrument affords, and he has demonstrated that the instrument is of great service.

In the first chapter Luys considers the necessity for the separation of the urines of the two kidneys. In the second chapter he describes the several methods hitherto employed for obtaining the urine from each kidney. In Chapter III the method of compression of one ureteral orifice is related. A description of the technique of ureteral catheterization and a criticism of the procedure is set forth. Chapter V describes different methods of separating the urines. Among these methods are those of Lambotte, Newman, Harris, Donnes, Cathelin, Jaboulay, and finally, the technique of the Luys apparatus is dwelt upon and a description of various experiments upon the cadaver is given. In Chapter VI Luys recounts why he thinks that the intravesical separation of the urine is advantageous as compared with the catheterization of the ureters. He bases the advantages upon physical, physiological and mechanical grounds. Chapter VII, the concluding chapter, is largely occupied by illustrative cases, recorded in considerable detail.

The book will well repay careful reading. The apparatus is simple, easily handled and apparently, with very few exceptions, efficient. The apparatus is made in this country by the Kny-Scheerer Company of New York.

The Luys separator consists of a staff, curved somewhat like a urethral sound, made up of three portions. The middle portion is a thin, solid metallic shaft, flattened from side to side. On each side of this, and completing the rounded staff, is a metal catheter almost semicircular in section. The two catheters upon their concave border of the curved portion have small openings into which the urine trickles — the two catheters applied to the central staff making a single instrument corresponding in size to a No. 21 French bougie. A little chain stretches across the concavity of the instrument, manipulated by a screw in the handle. This chain when not taut rests between the two catheters. The staff is covered with a rubber cot. After being introduced, the chain having been made taut, raises the rubber as a septum, filling the whole of the concavity of the curve of the instrument. The urine collecting on either side of the instrument trickles into the little holes in the silver catheters, and is collected at the distal end in separate tubes. The tricks of using the instrument are few, and after an occasional use of it are apparent. The convexity of the curved portion of the instrument is shaped to fit the floor of the bladder between the two ureters and the internal meatus of the urethra when the patient is in the semi-sitting position. The instrument is ordinarily used without an anesthetic. C. L. S.

The Internal Secretions and the Principles of Medicine. By CHARLES E. DE M. SAJOUS, M.D., Fellow of the College of Physicians of Philadelphia. Formerly Lecturer on Laryngology in Jefferson Medical College and Professor of Laryngology and Dean of the Faculty in the Medico-Chirurgical College. Volume I. With forty-two illustrations. Philadelphia: F. A. Davis Company. 1903.

Undeterred by the quoted words of Virchow, that "medical men are tired of the many new hypothetical systems that are thrown aside as rubbish only to be replaced by similar ones," the author in an octavo volume of seven hundred and eighty-eight pages presents an elaborate hypothetical conception of physiological and pathological processes.

In the construction of this work, fact and fancy are inextricably interwoven. In the preface the author states that "what we have said of the physiological chemistry of glycogen, myosinogen, urea and many other bodies, may not stand the scrutiny of an Ehrlich, a Gautier, an Abel, a Chittenden, a Vaughan; but the fact that such men are available to correct promptly what errors we might have made gave us confidence to proceed with our work without undue anxiety."

The author presents a great mass of data which he has collected from the writings of the leading investigators in anatomy, physiology and chemistry. From these collected observations surprising deductions are made by the author in support of his hypothesis. An idea of the nature and value of the work can best be given by a few excerpts.

The adrenals are considered as the key to tissue-respiration and also to the function of all organs now classed as ductless glands. "The secretion of the adrenals was traced as far as the pulmonary alveoli, but not beyond. Here it was found to hold in combination the various constituents of hemoglobin, and to endow both the latter and the plasma with their affinity for oxygen. Prevailing views as to the chemistry of respiration were thus radically transformed and our knowledge of the manner in which the blood-pigments were held together likewise." According to Sajous, contraction of the heart-walls is in great part due to oxygen-laden adrenal secretion. The adrenals are stated to be directly connected with the anterior pituitary body. "Indeed, this diminutive organ, hardly as large as a pea, and now thought to be practically functionless, proved to be the most important organ of the body, as governing center of the adrenals, and, therefore, of all oxidation processes. In general diseases what has been termed the patient's 'vitality' or 'vital resistance' thus becomes ascribable to fluctuations in the anterior pituitary body's functional efficiency. Symptoms of infection or poisoning are all manifestations, more or less severe, of overactivity or insufficiency of the adrenal system." The posterior pituitary body "proved to be the chief functional center of the nervous system." The pancreas and spleen are considered together, as "the secretions of these two organs unite in the formation of trypsin. A portion of the ferment passes into the splenic vein as an internal secretion and plays a leading part in all immunizing processes."

The Ehrlich's theories are greatly simplified by Sajous. The amboceptor is oxygen laden adrenal secretion and the complement is nothing more than trypsin. "The dominant active principle of antitoxin proved to be trypsin."

"The white corpuscles of the blood were found endowed with functions greatly exceeding in importance any as yet ascribed to them, even hypothetically. . . . Ehrlich's eosinophiles, non-phagocytic leucocytes asserted their identity as daughter cells, the separation from their parent cells, the neutrophiles, occurring in the liver by mitosis. They were traced to the pulmonary alveoli, where they participated in the formation of the nucleated epithelium. Their product proved to be hemoglobin."

This book has been reviewed in terms of praise by some of our leading medical periodicals. The publication of such works and their favorable review in representative journals will tend to discredit American medicine in the eyes of the scientific world.

AMERICAN EDITION OF NOTHNAGEL'S PRACTICE.

Diseases of the Intestines and Peritoneum. By DR. HERMANN NOTHNAGEL, of Vienna. Edited, with additions, by HUMPHREY D. ROLLESTON, M.D., F.R.C.P., Physician to St. George's Hospital, London, England. Authorized translation from the German, under the editorial supervision of ALFRED STENGEL, M.D., Professor of Clinical Medicine, University of Pennsylvania. Octavo volume of 1032 pages, fully illustrated. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

This new volume in Saunders' American edition of Nothnagel's Practice is the eighth to be issued, and appearing within two months after the publication of the volume on Tuberculosis, gives evidence that the publishers intend completing the series at an early date. This, one of the most valuable volumes in the series, is by the famous clinician Dr. Hermann Nothnagel himself, and is as exhaustive as it is practical. The distinguished editor, Dr. Humphrey D. Rolleston, of London, England, has used his pen most profusely, almost every page giving generous evidence of his careful editing. The editorial additions include sections on Intestinal Sand, Sprue, Ulcerative Colitis, and Idiopathic Dilatation of the Colon. Appendicitis and Peritonitis have been given unusual space, treatment and diagnosis receiving exhaustive consideration. The section on Intussusception has been greatly enlarged by the invaluable additions of D'Arcy Power of England, who has made this subject his own. There are 20 inserts of great merit.

The present volume is an important one, and after passing from the hands of its distinguished author has received due care and attention from the English and American editors.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, SEPTEMBER 15, 1904.

A Journal of Medicine, Surgery and Allied Sciences, published a Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for al foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

A HOSPITAL OBSERVATION LAW IN MASSACHUSETTS.

WITH the increasing complexity of social relations, it is inevitable that the questions relating to crime and insanity are likely to be more and more difficult of just settlement. To the end that the way may be as easy as possible both for the physicians and the courts, and that completest justice may be done the person charged with an offence, it is desirable that means of the most accurate observation during the pendency of a trial be provided.

In a recent paper, read originally in Boston and published in the last number of the *American Journal of Insanity*, Dr. Henry R. Stedman, on the basis of an important and confusing case of well-poisoning, expresses his views on the subject of a proper hospital observation law. The case itself does not particularly concern us at this time beyond the general fact that only after the last of many examinations was it possible to determine with assurance the actual insanity of the person charged with the crime. Taking this case as a text, and undoubtedly there are many like it, Dr. Stedman calls attention to the desirability of laws which will require that persons of this general character be under constant supervision in properly constituted hospitals for a sufficiently long time to determine their sanity or insanity. He holds that could such persons be under the eye and supervision of skilled alienists and of trained nurses, more prompt and accurate decisions could be reached and with less expense to the state than has hitherto prevailed. Three classes of persons he thinks would be affected by such a law, which he characterizes as follows:

(1) Patients who conceal their delusions. These cases are notoriously suspicious and persistently refrain from unburdening themselves to the examiners, so that many long interviews are often needed to gain their confidence sufficiently to elicit their false beliefs.

(2) Persistent feigning can also be far more easily and quickly detected under asylum conditions and surroundings than in jail, owing chiefly to the difficulty a prisoner experiences in keeping up the pretense of insanity uninterruptedly and consistently (as he must to be successful) where he is watched day and night by careful observers. Most malingering is, as we all know, bungling and readily exposed, but it is only with the utmost difficulty that really adroit feigning can be detected by the expert in occasional visits to the jail.

(3) Notorious capital cases. Here hospital observation as an adjunct to expert examinations must be of advantage in silencing popular clamor and alarm lest the prisoner escape just punishment through what is termed the "insanity dodge." The delay involved also tempers public opinion, as does the evident intent of thorough investigation shown in a term of hospital supervision.

The state of Maine has enacted a law of this sort which has been in successful operation for some years which has also been adopted by Vermont and New Hampshire. These laws provide that persons indicted for offences whose plea is insanity shall be ordered to the state hospital for the insane for observation. Such a law, in Dr. Stedman's opinion, is rather too sweeping in its provisions for the conditions as they exist in Massachusetts. The communities in this state are larger, and therefore a certain criminal element might be added to the atmosphere of insane hospitals which would be undesirable and a just cause for criticism. Removal to the asylum for the criminal insane is also manifestly unjust. Furthermore, the experts in Maine and New Hampshire are almost without exception members of the staffs of the state hospitals, whereas in this state many experts have no such connection with such hospitals. In view of these facts Dr. Stedman is of the opinion that provision should be made for "the occasional important and doubtful case only by enacting a law to the effect that at the request of the examining physicians the judge of the court before which a person is to be tried, for whom the plea of insanity is made, may order said person into the care of the superintendent of one of the state insane hospitals to be there detained and observed until further order of the court."

At the meeting of the Boston Society of Psychiatry and Neurology, held last November, where Dr. Stedman's paper was originally read, a committee, consisting of Drs. Folsom, Cowles, Channing, Jelly, Copp, Ayer and Stedman, was

appointed for the purpose of securing legislation. It is gratifying to note the fact that the efforts of this committee have resulted in the enactment of the following statute:

CHAP. 219, SECTION 11. "If a person under indictment for any crime is, at the time appointed for trial, or at any time prior thereto, found by the court to be insane, or is found by two experts in insanity designated by the court to be in such mental condition that his committal to an insane hospital is necessary for the proper care or for the proper observation of such person, pending the determination of his insanity, the court may cause him to be committed to a state insane hospital for such time and under such limitations as the court may order."

We have no question that this is a decided step in progress which should do much to obviate the undignified situations into which both physicians and the courts are often forced.

BOSTON CITY HOSPITAL REPORT.

THE report of our chief city medical institution is always a document of interest. This year the fortieth report brings the history of the hospital up to Jan. 31, 1904, and fills a pamphlet of 186 pages, embellished with two admirable charts of the hospital buildings and a number of illustrations in the text. The changes in the personnel of the staff during the past year have been numerous through promotions and resignations, as is natural in so large an institution, among the resignations being that of Dr. John C. Munro to take charge of the surgical department of the Carney Hospital. The office of physician for infectious diseases has been created, and Dr. J. H. McCollom, long identified with the South Department of the hospital, has been appointed consultant in such cases. The trustees in their report call attention to the fact that during the year the new out-patient building and a pavilion for the hospital have been completed, but, owing to lack of funds, the occupancy of these buildings has been temporarily deferred. When the new surgical out-patient building shall be occupied, it is proposed to renovate the building devoted to medical out-patients, and when this is done, the hope is expressed that there will be no demand for additional room for the out-patient service for several years. Speaking of the South Department, the trustees state that during the nine years it has been in commission it has treated 21,387 persons ill with some infectious disease. As the work of this beneficent department of the hospital has grown, the need of further accommodation for patients has become increasingly apparent. Difficulty, has, for example, been experienced through the mixed infections resulting from the classification of patients as at present necessitated. Many cases of measles have also been admitted, although there is no special building for this relatively innocuous disease. The trustees are perfectly aware of the need and are of the opinion that an additional building, at a probable expense of approximately $125,000, should be erected as soon as possible. The work of the pathological department, the trustees particularly commend, and make the following liberal statement regarding the necessity of a pathological laboratory and its appurtenances as an integral part of the modern hospital: "The trustees are very glad to co-operate in scientific research, believing it to be the duty of all first-class hospitals to aid to the utmost everything that furthers the advancement of medical science. Patients in a large, general hospital, having a well-equipped pathological laboratory, receive more scientific treatment, more careful investigation and professional study, and better nursing than in those without one. In fact, no hospital is complete to-day, without a laboratory conducted by skilful physicians and pathologists." This attitude of the trustees, as expressed in the foregoing statement, has done much to make the hospital what it is. Dr. Rowe's report as superintendent of the hospital covers adequately, as heretofore, points in administration and in general hospital development. A large part of the volume, as is usual, is taken up with medical and surgical statistics, which, as we have previously had occasion to remark, have been of very much increased value since the adoption of a systematic plan of classification. The report in general is an exemplification of a modern municipal hospital of the highest character.

A MEDICAL RECREATION SOCIETY.

IN a recent address as president before a New England medical society, Dr. E. R. Campbell of Bellows Falls made certain suggestions to which we wish to call attention. After discussing various matters of significance to practitioners everywhere, he drew his hearers' attention to the benefits of what he termed "the medical society habit." The medical society he regarded as a kind of post-graduate school, wherein the expression of diverse opinions might be made of practical value to physicians. He urged upon his hearers to make the medical society habit contagious, and hoped that the infection might spread to the seventy-seven thousand physicians

in the United States who are said to belong to no medical society whatever. We are heartily in accord with this opinion of Dr. Campbell, which, if not original, is certainly of the very first importance for the uniform development of our practitioners. The point, however, in his remarks to which we desire particularly to revert is what he terms a New England medical society, which shall act as a summer school of medicine in connection with a short vacation. He suggests that physicians leave their practices absolutely for a certain period to congregate at some point in the New England states where pleasure may be combined with a certain amount of literary work, urging that such an organization would prove to be not only of professional benefit, but conducive to much social pleasure and recreation.

Dr. Campbell's idea, as elaborated much more fully in his address, is one worthy of consideration. We have for a considerable time noted the tendency of combining with the somewhat heavy side of our medical meetings a degree of recreation which not many years ago would have been thought impossible. We note that the place of medical meetings is chosen with care to this end, and that the programs suggest not only attendance upon the meetings, but also possibilities of various quite extraneous amusements. This tendency we have always commended, and certainly, if Dr. Campbell's plan of instituting a society, which shall have as its professed aim recreation as well as profit, can be organized, it would fill a well-defined need. It is, however, a question whether it is not wiser to stimulate existent societies to a further recognition of the desirability of recreation rather than to constitute an entirely new one for that purpose. Our existent summer schools, as we have observed them, offer admirable opportunities for other pursuits than medical work in cities and towns well adapted for the frivolities, and this over a period of several weeks. In general, however, the development of the plan suggested is one to which we are glad to give our support.

MEETING OF SOCIETY OF CHEMICAL INDUSTRY.

In closing an address at the banquet given in honor of the Society of Chemical Industry at the Waldorf-Astoria on Sept. 8, Sir William Ramsay, President of the Society, made a statement which was regarded as of great significance by his auditors. It was as follows: "It seems to me that we may be on the eve of the discovery of the origin of the ordinary elements which may be the products of the breaking down of radio-active elements of high atomic weight." Among the distinguished foreign chemists present were Professors Oscar Leprecht of the University of Berlin, and Hugo Münsterberg, and Ostwald of the University of Leipsic. During the session of the society, Prof. Ira Remsen of Johns Hopkins University was presented with a gold medal for the most important discovery of the year in chemistry. At a business meeting Mr. Nichols of New York was elected president of the society for the ensuing year. This is the second time that the honor has been conferred upon an American, Prof. Charles Chandler of Columbia University having been the first of our countrymen to receive it.

MEDICAL NOTES.

Dr. E. L. Munson.— The following statement is made in the last report, which has come into our hands, of the Board of Health for the Philippine Islands: "The Board of Health has been unfortunate in losing the services of Dr. E. L. Munson, captain and assistant surgeon, United States Army, who, as Assistant to the Commissioner of Public Health, rendered very faithful and efficient service to the cause of sanitation in the Philippine Islands. Captain Munson's health became impaired by overwork, and he found it necessary to return to the United States for treatment. He had to leave undone many things which he had planned, but the work that he accomplished and the influence which he exerted upon the cause of sanitation in the Philippine Islands will remain as permanent testimonials to his zeal and knowledge." Dr. Munson has been a valued contributor to this Journal. We regret exceedingly to hear of his illness, which it is hoped may be benefited by a return to this country.

Wellcome Chemical Research Laboratory at St. Louis. — Among the exhibits in St. Louis of importance for medical men are two, numbered 14 and 15 respectively, in the British section, illustrative of the work being done by the Wellcome Chemical Research Laboratories and the Wellcome Physiological Research Laboratories in London. The work undertaken in these laboratories — founded by Mr. Henry S. Wellcome in the year 1896, and since then under the direction of Dr. Frederick B. Power — has been of a most varied character and wide range, representing almost every department of chemical and phar-

maceutical science. The investigations have comprised, for example, the devising of new methods of analysis, the examination of drugs of reputed medicinal value from distant lands, Africa, India, and the Fiji Islands, as well as those indigenous to Europe and North America, in order to determine both the nature of their active chemical constituents and their pharmacognostical characters; the study of the constituents of various essential oils; the constitution of some of the more important alkaloids and other chemical substances of special therapeutic value; and the preparation of new chemical compounds by synthetic methods, both chemical and electrolytic.

MEDICAL PROGRESS IN THE PHILIPPINES. — The following statistics taken from a recent monthly report of the Board of Health for the Philippine Islands gives one an idea of the vigorous sanitary and medical work going on there.

In the work of sanitary inspections there were 5,302 inspections and reinspections of houses during one month, 329 houses were cleaned as a result of sanitary orders, 35 whitewashed or painted, and 95 disinfected. A total of 669 yards were cleaned and placed in good sanitary condition. There were 32,409 rats destroyed in the prophylactic measures against plague. Two hundred and sixteen thousand seven hundred and sixty-five units of vaccine virus were issued, and 13,251 vaccinations were performed in the city of Manila. During the month Dr. Edward L. Munson, captain and assistant surgeon, U. S. A., who was detailed to this office as assistant to the Commissioner of Public Health, prepared and put in operation a comprehensive and carefully prepared plan which has for its purpose the vaccination of all the inhabitants of the Philippine Islands. If the work as outlined is carried out it is hoped that smallpox will play little part in the reports of infectious diseases of the future. A veterinary division was established which will have direct charge of all matters pertaining to veterinary medicine and surgery throughout the Philippine Islands. Dr. Munson has since returned to the United States.

CANDIDATES FOR STATE REGISTRATION. — It is announced that eighty-eight candidates have taken the September examination for registration in medicine in Massachusetts. This is regarded as a large number for this time of the year, but a considerable proportion are candidates for re-examination. Announcement of successful candidates will be made the latter part of this month.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon Sept. 14, 1904, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 47, scarlatina 2, typhoid fever 50, measles 1, smallpox 0.

NEW YORK.

PREVENTION OF SUICIDE. — At a meeting of the Board of Health held Sept. 7, an amendment made by the Board was announced which will, no doubt, have a salutary effect in the prevention of suicide. This ordinance forbids the sale of carbolic acid, when in a stronger solution than 5%, except when ordered in a physician's prescription.

ARRIVAL OF PROFESSOR ORTH. — Prof. Johannes Orth, the successor of Virchow at the University of Berlin and consultant in the operations performed some time ago on Emperor William's throat, arrived by the steamship "Zeeland" on Sept. 5. He was met at the dock by Prof. Thomas Cullen of Johns Hopkins University and Dr. Paul M. Pilcher of Brooklyn, two of his former pupils.

UNIQUE ESCAPE FROM DEATH. — By the prompt action of Joseph McSweeney, a tenement house inspector, the lives of two men were recently saved in the Brownsville district of Brooklyn. They were Italians engaged in making an excavation upon whom a great mass of loose earth had fallen, and McSweeney, with the help of some workmen, succeeded in getting down to them a piece of rubber hose which had been used as a water pipe in mixing mortar near by. By this means they were supplied with air until their rescue could be effected.

NEW PAVILION, ST. MARY'S HOSPITAL. — The new pavilion of St. Mary's Hospital at Jamaica, Borough of Queens, was opened on Sept. 5, with appropriate ceremonies. It is built of brick and stone, 116 by 34 feet, and has three stories and a basement. Its cost was $75,000, and it is stated to be the finest hospital structure on Long Island, outside of Brooklyn. It affords accommodation for seventy-five patients, and the site allows for two other pavilions to be erected in the future. The total capacity will then be three hundred.

ATHLETIC EXHIBITION. — On Aug. 31, eight hundred young athletes, some of the boys and girls who for two months had made up the classes in the Board of Education's great summer playground school, gave an admirable exhibition in the grounds located under the Manhattan

end of the new Williamsburg bridge over the East River. Mr. Evert Jansen Wendell, who is still remembered as a distinguished sprinter at Harvard, acted as the judge of the various events. On Aug. 30 a playground, exclusively for girls, the first in the history of the city, was opened in Tompkins Square. This playground, which occupies an acre and a half, has been equipped at an expense of $700 and is to be open throughout the year.

A Public Athletic Field. — A large athletic field, provided by the city, was opened to the public on Sept. 10, by Mayor McClellan in the presence of 30,000 spectators. It is located in Pelham Bay Park, in the Bronx, and consists of 120 acres, twenty acres of which are devoted to a parade ground. It also includes ample bathing and boating accommodations on Long Island Sound. A feature of the undertaking is an emergency hospital tent, where prompt surgical aid will be afforded to persons injured in the park. The credit for the whole scheme is largely due to Mr. William P. Semidt, Park Commissioner of the Borough of the Bronx, who raised $8,000 by personal subscription among his friends to defray the expense of the opening ceremonies, which included medals for a large number of athletic events.

Quarterly Death Statistics. — The condensed quarterly report of the Bureau of Records of the Health Department, just issued, shows that the number of deaths for the second quarter of 1904 was 21,100. This mortality, on an estimated population of 3,838,024, gives a death-rate of 22.08 per thousand, as compared with an average number for the same quarter of the five preceding years of 16,919 deaths; which, on an estimated population of 3,540,664, gives a death-rate of 19.15, an increase of 2.93 points. The principal causes of this increased death-rate are regarded to have been: (1) The effect of the protracted measles epidemic, which, beginning in December, 1903, did not diminish in severity until the early part of June, thus increasing the number of deaths from acute respiratory diseases; (2) the prevailing influenza, furnishing considerably above its average quota of deaths, as reflected in the unusually large mortality from pneumonia, Bright's disease, and pulmonary tuberculosis; (3) a severe epidemic of cerebrospinal meningitis, showing itself in the month of March and continuing throughout the quarter; and (4) the "Slocum" disaster, in which over 900 lives were lost. The increased number of deaths occurred at all ages, among children under five years, adolescents, adults and old people.

Miscellany.

THE NEW SURGICAL BUILDING OF JOHNS HOPKINS HOSPITAL.

According to the New York *Medical Journal*, elaborate preparations are being made for the dedication of the new surgical building of the Johns Hopkins Hospital on the morning of Oct. 5. The structure is now practically ready for occupancy.

The building cost about $150,000, is of brick, has four stories, and is believed to be admirably adapted for teaching. Sanitation and ventilation have been important considerations in every feature of the structure. All the floors are of tiles, every room and hallway used by patients being also wainscoted with glazed white tiles as high as a man can reach. The stairways are of marble and iron, and there are fine toilet rooms and baths on every floor. A surgical amphitheatre forty feet high also has extensive tiling, marble work, and a hall, with wide lights, composed entirely of wired glass. There are a number of rooms for consultation. The principal feature of the building is the surgical amphitheatre, which is situated on the third and fourth floors. There the operations which are watched by the medical students will be performed. The conical incline with the seats is composed entirely of tiles and marble. The parapets in front of the seats are white enameled sheets of steel supported by narrow iron stanchions, and the seats are supported by iron bars from these plates. In order to cleanse the room all that is necessary is to turn on the hose and the incline carries the water to the bottom of the amphitheatre, where it is run into a drain. The amphitheatre is entered by the students at the fourth floor. The operating rooms, which open into the bottom of the amphitheatre, are at either side on the third floor. There are two operating rooms, in both of which a superior system of heating and ventilation is installed. The air enters the shaft from the outside and is conducted to a box in the room containing the radiators. From the radiators the air escapes gradually to the room through a metal mesh, or filter, and thus a draft of air upon the patients is prevented. On the third floor there are also waiting rooms for the patients in beds, washing rooms, dressing rooms for the surgeons, and preparing rooms. There is a room for surgical pathology and a private office for Professor Halsted, head of the surgical department. On the second floor there are a number of smaller apartments which will be used as consulting rooms on the surgical cases, each room or suite of rooms being furnished with handsome toilet sooms and baths. Here, too, is a surgical lecture room, a large, fine auditorium which will be used by Dr. Halsted and his assistants in addressing the surgical classes. On the first floor, which is entered from Monument Street, will be emergency rooms for accident cases, minor operation rooms, the orthopedic department, and the fine clinical lecture rooms, over which Dr. William Osler presides. This latter room is said to be one of the finest lecture rooms connected with any medical institution. Like the surgical amphitheatre, it is from thirty-five to forty feet high, and will be lighted on the north side by long windows. It can be entered from the first and second floors. The patients brought to the operating rooms from the hospital must be carried to the third floor of the surgical building, and for this purpose a hydraulic elevator of special construction has been installed. The surgical records are to be placed for storage in two fire proof vaults.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, SEPTEMBER 3, 1904.

CITIES.	Population Estimated, 1904.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from				
				Infectious diseases.	Acute lung diseases.	Diphtheria and croup.	Typhoid Fever.	Diarrheal Diseases.

Deaths reported, 3,092; under five years of age, 1,152; principal infectious diseases (smallpox, measles, scarlet fever, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption) 1,083; acute lung diseases 184, consumption 360, scarlet fever 14, whooping cough 15, cerebrospinal meningitis 12, smallpox 1, erysipelas 2, puerperal fever 4, measles 4, typhoid fever 51, diarrheal diseases 567, diphtheria and croup 53.

From whooping cough, New York 5, Chicago 3, Philadelphia 2, Baltimore 1, Pittsburg 2, Boston 1, Lynn 1. From measles, New York 3, Pittsburg 1. From scarlet fever, New York 5, Chicago 3, Philadelphia 1, Baltimore 4, Pittsburg 1. From cerebrospinal meningitis, New York 10, Chicago 1, Worcester 1. From erysipelas, Philadelphia 2. From smallpox, North Adams 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,271,287, for the week ending Aug. 20, the death-rate was 22.7. Deaths reported 6,639; acute diseases of the respiratory organs (London) 40, whooping cough 79, diphtheria 39, measles 130, smallpox —, scarlet fever 26.

The death-rate ranged from 7.8 in Kings Norton to 39.1 in Liverpool; London 21.6, West Ham 28.0, Brighton 17.3, Plymouth 17.8, Bristol 16.0, Birmingham 24.4, Leicester 21.2, Nottingham 23.9, Bolton 16.9, Manchester 26.9, Salford 32.1, Bradford 17.0, Leeds 23.5, Hull 29.0, Sheffield 22.4, Cardiff 17.2, Rhondda 30.7, Merthyr Tydfil 20.1, Swansea 27.7, Wigan 34.0, South Shields 17.0.

METEOROLOGICAL RECORD.

For the week ending September 3, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 10, 1904.

J. F. URIE, surgeon. Detached from the "Missouri" and granted sick leave for three months.

N. H. DRAKE, surgeon. Detached from the "Lancaster" and ordered to the "Hancock."

M. S. GUEST, passed assistant surgeon. Ordered to the "Lancaster."

C. M. DEVALIN, passed assistant surgeon. Unexpired portion of leave revoked; ordered to duty at the Naval Hospital, Philadelphia, Pa.

THE BOSTON CITY HOSPITAL.

The following operations will be done and cases shown in the amphitheatre of the Boston City Hospital on September 16th, from 10 A.M. until 12.30 P.M.: Carcinoma Breast; Tumor Breast; Tuberculous Peritonitis; Breast Abscess; Inguinal Adenitis; Inguinal Hernia; Interval Appendix.

RECENT DEATHS.

EDWARD P. BUFFET, M.D., of Jersey City, died on Sept. 9, of cardiac disease. He was born in Smithtown, Long Island, of Puritan ancestry, Nov. 7, 1833, and was graduated from the College of Physicians and Surgeons, New York, in 1858.

JOHN T. BROSNAN, M.D., of Brooklyn, N. Y., died on Sept. 9, after a long illness, at the age of thirty-five. He completed his collegiate education at St. Francis Xavier College, New York, and was graduated from Bellevue Hospital Medical College in 1893.

BOOKS AND PAMPHLETS RECEIVED.

Clamp and Cautery in Appendectomy. By Joseph Rilus Eastman, M.D. Reprint.

Tuberculosis of the Urinary Tract. By Edgar Garceau, M.D. Reprint.

A Handbook of Pathological Anatomy and Histology, with an introductory section on Post-mortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By Francis Delafield, M.D., LL.D., and T. Mitchell Prudden, M.D., LL.D. Seventh Edition. Illustrated. New York: William Wood & Co. 1904.

Clinical Lectures on Mental Diseases. By T. S. Clouston, M.D. Edin., F.R.C.P.E. Sixth Edition. Illustrated. Philadelphia and New York: Lea Brothers & Co. 1904.

The Prevention of Typhoid Fever. A Paper Presented at the One Hundred and Twelfth Annual Meeting of the Connecticut Medical Society, May 26, 1904. By William G. Daggett, M.D. Reprint.

A Medico-Legal Case of Well-Poisoning, with a Plea for a Hospital-Observation Law. By Henry R. Stedman, M.D. Reprint.

The Student's Handbook of Surgical Operations. By Sir Frederick Treves, Bart., K.C.V.O., C.B., LL.D., F.R.C.S. New Edition. Revised by the Author and Jonathan Hutchinson, Jun., F.R.C.S. Illustrated. (Abridged from the Author's "Manual of Operative Surgery.") Chicago: W. T. Keener & Co. 1904.

Address.

THE TENDENCIES OF THE PRACTICE OF MEDICINE AS A PROFESSION AND AN ART.*

BY LEWIS M. PALMER, M.D., SOUTH FRAMINGHAM, MASS.

MR. PRESIDENT AND MEMBERS OF THE SOCIETY:

Knowing too well that I have no special knowledge on any medical or surgical subject that would justify me in asking your attention for an hour to-day, I have chosen for a theme, "The Tendencies of the Practice of Medicine as a Profession and an Art." I do not expect to instruct you, for I have no instruction to give. I shall emulate Mark Twain, where he says in one of his prefaces that he should try and impart no knowledge, but if he failed it would be because, under great pressure, he leaked some, in spite of his efforts to the contrary. I shall measure my success by the times I see you look at your watches, or the clock, to see how much longer it is before the time of the real object of this meeting, "the dinner."

After a quarter of a century of study and practice of our noble profession, I am ready to say, with a partial knowledge of failures, weaknesses, and limitations, that it is the noblest profession of all. I would not for a moment belittle the profession of the minister of God. No higher ideal can be conceived than to be a beloved pastor of a people, leading them by example and precept to a higher plane of thinking and living. We all of us, perhaps, have had occasion, in some inexplicable tragedy of life, to turn to him for some words of comfort, or hope or cheer, and we remember with gratitude what he has been to us and done for us. But when I remember what travail of soul, worriment of mind, and physical strain it has caused me to write one sermon, on which I had a whole year's time, I have tried to imagine what the strain and work must be to grind out two sermons a week on the same great theme, and always have them new and fresh and interesting, and not too pointed about personal shortcomings.

A prominent lawyer friend of mine says he thinks he could write about four good sermons, and after that he should be entirely pumped dry. No, friends, high and noble as is the calling of a minister, I think I prefer to it the carping and unreasonable criticism of ignorant patients, or be amused by the untellable things that occur in every busy doctor's life.

While much in the legal profession is high and noble, it seems to me that far too much of its work consists of making and fostering needless strife between man and man, to make it desirable. It is supposed to deal with right and justice and equity, but its noble ideals are besmirched by the quack of the legal profession, the pettifogging lawyer, who scents accident and trouble as the buzzard does the carrion, and like him, ever hovers about. More than once, in time of accident, have we had difficulty in our little Framingham Hospital, in keeping out these legal buzzards, and I have often wondered what would be said of us as doctors if, in like manner, in time of accident, we were to rush to these poor unfortunates and say, "Employ me, employ me, and I will save you."

My attention has been recently called by an eminent judge to another remarkable difference between the legal and medical professions. He says: "You, as doctors, are always looking ahead for the new thing, scientific fact, or discovery, while we lawyers and judges are always looking backward, hunting after a precedent." I think I prefer the profession that looks ahead for better things, instead of looking backward, banking on the wisdom of ancestors.

An ancient scholar has this exalted praise for the physician: "Man in nothing comes nearer to the gods than in giving health to his fellow-mortals." In the advance of civilization, and the wonderful progress of scientific knowledge along all lines of human thought, in none has there been a more wonderful result seen than in medical, and especially surgical, knowledge. As we like to revisit places that we have seen many, many times because of their associations, or read and reread a beautiful poem because it expresses a tender sentiment in language which appeals to our experience, or as we love to hear again and yet again the same old melodies, and be carried for the time being beyond our narrow, sordid lines by the harmonies of some of the symphonies or oratorios of the old masters, so do we enjoy hearing the story of the progress of medical thought from the mysticism and superstitions of former times to the present so-called scientific age. But with all this wonderful advance, and with all our boasted knowledge, it seems to me that in some respects we as practical physicians, seeking all possible sources of aid, are woefully deficient.

We live in an age of materialism. We are attempting to account for all conditions and manifestations on a material basis. We glory in the fact that everywhere are springing up, like the flowers of spring, laboratories and educational institutions, endowed with some of the wealth of both honestly and ill-gotten gain, searching with the enthusiasm of the true scholar after the gem of gems — truth. Thousands of the keenest intellects, stimulated by ambition, by love of knowledge, and influence of mind upon mind, are spending their lives in biological, physiological and pathological scientific research. Myriads of eager eyes are peering ceaselessly through the microscope, looking for the festive germ, which is to account for all that is amiss or awry in this otherwise would-be perfect world of ours. Still other thousands are patiently and impatiently experimenting in the laboratory, at the bedside and in the clinic with disorganized humanity, looking for the elixir of life, or the panacea for all diseases.

The versatile Beecher once foolishly said that there grew within the sight of every man's grave

* Annual Address read before the South Middlesex District Medical Society, April 20, 1904.

some herb which, if rightly understood and applied, would have saved his life. Before and since that time there has been given for the cure of the sick, at some time or season, everything conceivable and inconceivable, in the heavens and on the earth, mineral, vegetable and animal, in the sea and beneath the sea, as well as the organic extracts of man and beast.

The pathologist has contended that all was diseased, and the Christian Scientist positively asserts that there is no such thing as disease. The specialist has searched for and found the trouble in his limited field, the surgeon has gradually dismembered the sufferer, till the marvel is how little of the original plan is necessary for existence; formerly the ovary was the *bete noire* of female happiness, but now the appendix and the gall bladder hold the centre of the stage. The physical culturist has exercised the patient; the neurologist has put him to bed; the dietarian has starved him; the Weir Mitchells have stuffed him; the hydropaths have deluged him inside and outside with water; and the orthopedist has baked him; the osteopaths have boned him and the quacks have fooled him; the homeopaths have given their thirty dilutions or infinitesimal doses, and the regular physician has given him a dose a million times as large; and all these treatments in the majority of the cases give practically the same results, for as Oliver Wendell Holmes once wittily said to a company of surgeons: "There's a Divinity that shapes our ends, rough hew them as we will." If this be true, as perhaps some of you will question, why is it true? I answer because a large part of our cases will get well, if let entirely alone and given a fair chance. You remember Mr. Dooley said: "If the Christian Scientist had some science, and the doctors more Christianity, it wudden't make any diff'rence which ye called in, if ye had a good nurse."

People are governed chiefly through their fears and prejudices, and not by their hopes. It is a very strange fact to me that from the medical schools and the masters and teachers, down through to the humblest practitioners, it is practically forgotten and ignored that man is a complex being; more than physical and material, or a complicated machine; that he has not only a body, but also at least a mind, if not a soul, whatever that may mean. There is an old Latin saying, which I think is not true, that where there are three doctors, there are two atheists. Personally, I am happy to say that I believe that man has not only a body and mind, but also a spiritual or moral nature, or soul. The how, the what, the where, and the whither of this third part of our nature I will not attempt to sermonize upon, or to teach to you. Maturity develops a belief in it. Of the mentality part of our nature, however, there can be no question, but its relation to and connection with the physical body is still a mystery. How vividly I remember my keen disappointment when a medical student, when the professor in physiology lectured upon the brain. He had told us of the functions and relations of the other organs of the body, and now was explaining those of the brain. In my interest and eagerness to have some things made clear that had always been dark, I forgot to take notes, and was all anticipation when the professor stopped and said: "But, gentlemen, here we have to stop; for how the mind exists and works and thinks in these brain cells we do not know." Even now I never make an autopsy or see the wonderful brain that I do not wonder and ponder over the same old subject.

But that the mind does exist and act and connect, and is dependent upon and interdependent with the body, is beyond question. The most of us can recall the days when we have done the most good have been the days we haven't opened our medicine case, if we carry one, or written a prescription, if we are more *toney* than economical. We have done it by removing groundless fear in A, in advising B, in restraining C, in encouraging D, and poking fun at E.

Can mental impressions and conditions cause disease? To answer that question, let us consider some of the familiar experiences of daily life. Pleasurable emotions, excitement, or shame will flush the face by dilating the superficial blood vessels, while fear or nervous shock will contract them and make one turn pale; and sudden and terrible bad news will so inhibit the heart's action as to stop it and cause death. Your critical attention gives me, just now, a bad attack of tachycardia. Grief and worry will stop entirely digestion, while later, to-day, the sociability of the banquet table will allow you to make pigs of yourselves with impunity. The whipped dog or the public singer or speaker has polyuria. The woman in labor will lose her pains on the coming of a new doctor, or any unusual excitement. The doctor will go with safety and impunity into all kinds of contagious and infectious diseases, while the fear-stricken laity will succumb while they are yet afar off.

It is a well-recognized fact among military men that an army is much more liable to sickness and disease after a defeat than after a victory. A woman in anger may poison her milk to the danger of her child. I knew a woman, young and healthy, midway between her monthly periods, when unexpectedly confronted by a tough-looking tramp, to have a tremendous gush of blood from her uterus.

But why need I cite further cases? They are familiar to you, and you can add to them out of your own knowledge and experience. If a momentary mental condition will give a temporary disturbance of function, then a prolonged bad mental influence will give a prolonged disturbance of function or disease. If disease is a lack of harmony in the functionating processes of life, then it looks to me logical that the proper cure for diseases caused by mental conditions is to remove the cause as far as possible, and use those agents that will best cure or correct the bad results.

When I write my prayer-book, I shall have as one of the leaders, "From hysterical women and hypochondriacal men, Good Lord, deliver

us." But if we belong to that class whose prayers don't avail much, and we still have such for patients, what shall we do with them? The love-sick maiden comes to us with a long story of nervous troubles, and we attempt to cure her by giving her phosphorus, when it isn't phosphorus she lacks or wants. Later in life she marries a beast, fondly dreaming she was wedding a man, and her later condition is worse than the first. Then, instead of killing the man, we give the poor wife valerian or assafetida. The hypochondriacal man imagines all sorts of things, and makes mountains out of mole-hills, and we give him — well, what would *you* give such a man?

The tendency of the medical profession of to-day is to look to the laboratory as the supreme court in medical science. In many things I admit that it is, but on the other hand, in many more things I contend that it is far from it. I desire not to be misunderstood. The laboratory has done, is now doing, and will in the future do more wonderful things, but it is only a part of our fighting force. There can be no question about the truthfulness of the germ theory, and its being a causative agent in the production of many diseases, especially the so-called infectious or contagious diseases, and others yet to be demonstrated, but the care of these is relatively a small part of our life's work. The trend is toward absolute materialism.

Sir James Paget said: "A physician's exclusive duty should be to study men as men, to master the marvelous intricacies and dependencies of spirit, soul and body, and to be sufficiently skilled to know when and how to call on the one to help the other, and with such men the profession would be complete." Sir Benjamin Brodie said: "It is the business of every practitioner of medicine to study not only the influence of the mind upon the body, but also that of the body upon the mind."

Neurotic affections of both children and adults are increasing and multiplying to an alarming extent, because more nervous energy is now expended in a decade, with modern high pressure living, than in a century of the good old times. The results are inevitable and lamentable. Psycho-therapeutics is a very important but a very poorly understood branch of our profession. It is yet in its infancy and a feeble child at that. Personally, I think there should be in every medical school a chair of psycho-therapeutics, which should include in it psycho-physiology and psycho-pathology. We have now bright lights in this field, among whom I would mention Gowers, Weir Mitchell, Charcot and others.

In this field the common people are dissatisfied and wiser than the profession. The neglect of this mental factor in medicine has been probably the direct cause of the multitude of fads, past and present, such as mental science, spiritualism, clairvoyance, mind cure, hypnotism, mesmerism, Dowieism, and the last two and most popular cults, namely, osteopathy and Christian science. I have done much reading and thinking on these fads the last year, and am ready to exclaim as did Hamlet to Horatio: "There are more things in heaven and earth than are dreamt of in your philosophy."

I have looked up with more or less care osteopathy. I have relied chiefly upon an article by J. Martin Littlejohn, an Englishman with many titles, and whose article was approved by a local osteopath as representing their ideas. Osteopathy was first formulated by Andrew Taylor Still, M.D., in 1874. Dr. Still claimed "that a natural flow of blood is health; that disease is the effect of local or general disturbance of the blood; that to excite the nerves causes muscles to contract and compress the venous flow of blood to the heart, and that the bones could be used as levers to relieve pressure on nerves, veins, and arteries."

Osteopathy aims to correct rib and vertebral displacements, to correct tissue contracture or displacement, so that when the tissues and bones are restored to their normal position and function, nature may resume its normal activity. In the removal of these obstructions, irritations and hindrances to free activity, they claim, lies the secret of osteopathic success. To sum up briefly what I gather of the system, if it can be called such, it is that they believe, or pretend to believe, that sickness is all or nearly all due to irregularities and displacements of bones, muscles, nerves and tissues, and by remedying these defects, sickness can be removed. To any one who knows anatomy, or has had experience as a surgeon or in the autopsy room in moving or removing a vertebra or any large bone from the place where the Lord put it, it seems a huge joke to think of trying to move any such bone through skin, fascia, muscle, tendon and cartilage. Only a mythical Cyclops could do that stunt. If they would honestly do away with the quack claim of cause, and practice and honestly claim results from legitimate massage, then they could accomplish wonders, and claim, deserve and have the respect of those who are searching after truth, wherever it lay.

Along this line of thought, I have also, in the preparation of this paper, read much concerning Christian Science. Now please don't do as perhaps you are in the habit of doing, say it's all nonsense, only a fad, that will soon pass. Not so fast. Have you ever looked it up and given it the same considerate investigation that you have other subjects? If not, I want to advise you to do so, not only to see for yourself what there may be in it, but also as an exercise in mental gymnastics to see what stunts your mind is equal to. I am ready to confess that though I am a college-educated man, been a teacher many years, done some public speaking, and under ordinary circumstances think I have a fair, average knowledge and use of the English language, yet when it comes to grasping and assimilating what the most of the Christian Science writers say, I am a monumental failure. I don't know whether I lack mentality or spirituality, or some other "ality," yet this I do know,— I can't see what they are driving at.

With some of the writers I found the sense was the same whether I began in the middle or at the end, or the beginning. It has reminded me of the old lady who read the dictionary through as a story book, who, when asked how she liked it, said, "Wall, it was all very interesting, but I couldn't see the connection." Mrs. Eddy, or as her quasi-worshipers call her, "Mother Eddy," the author, says Christian Science is the essential religion that Christ came to establish, but has been lost for centuries, but was rediscovered by her in 1866.

It is supposed to be founded on the Bible, but is a revised or up-to-date exposition of the same, as set forth in a book called "Science and Health, with Key to the Scriptures." Some of her followers claim that the simple reading of this book has cured them.

Let me give some of the striking and absurd thoughts or quotations from this book: "Christian Science is the Holy Ghost, the Comforter." "Jesus was the offspring of Mary's self-conscious communion with God." "The union of the two sexes is not required to create the rest of the human family" (page 524). "That our body is material, and as body should suffer, is but a delusion." "The body can never be weary, any more than a wheel" (114). "Food does not affect the real existence of man" (387). "Food neither strengthens or weakens the body" (118). "Lungs never sustained existence" (423). "Man is incapable of sin, sickness, or death" (471). "Disease is but fear made manifest in the body" (372). "Sickness is a dream from which the patient needs to be awakened" (415). "Ossification or any unusual condition of the body is as directly the action of mortal error as insanity. Bones have only the substantiality of thought which formed them. They are only an appearance, a subjective state of mortal mind" (421). "Inflammation, tubercles, hemorrhage, and decomposition are beliefs, images of mortal thought. They should be treated as error" (422). She says further: "The lightning is fierce and the electric current swift, yet in Christian Science the flight of the one and the blow of the other are harmless" (262). "Electricity is some of the nonsense of error" (259). "The unreal offspring of finite mind" (610). Again, she says: "She had already in her possession well authenticated records of the cure by herself and her students, through mental surgery alone, of dislocated joints and spinal vertebræ." Again she says: "A farmer chopped off his forefinger at the first joint and came to her for treatment, and that she made his finger whole, giving him a new bone, new flesh and a new nail." One of the most interesting and sane claims that Mrs. Eddy makes is the following: "Christian Science demonstrates that the patient who pays whatever he is able for being healed is more apt to recover than he who withholds a slight equivalent for health" (300, 301). That's common sense.

I could give you plenty more of interesting quotations, but perhaps what I have already given will suffice. Christian Science claims to cure all manner of diseases, and yet they say that sickness is only a dream and disease a fear.

A Mr. E. A. Kimball of Chicago, a teacher of Christian Science in the Boston Metaphysical College, said in a lecture in Boston last fall: "The practice of Christian Science is in its infancy. No pretence is made that such proficiency and efficiency have been attained by practitioners as to preclude any failure, but already this practice has resulted in the cure of practically every disease that is in the long list of incurables. In other words, Christian Science can heal all diseases that drugs have ever healed, and all that drugs have never healed, hence the Christian Scientist contemplates sickness as something he has a right to cure and ought to be able to cure."

Yet, personally, I have never known them to make a single cure, or even known of a well-authenticated cure of any serious disease.

Dr. John B. Huber of New York recently attempted to investigate twenty of their remarkable cures, but in no instance was he able to get the necessary facts by which their genuineness could be tested. He then wrote politely a series of questions to Mrs. Eddy. She did not reply, but, several weeks later, her counsel, Judge Hanna, wrote him, saying: "Study earnestly the Bible and 'Science and Health, with Key to the Scriptures.'"

I have given you some of the glaring nonsensical statements or quotations from the Christian Science textbook to show their inconsistency, yet I have no hesitation in saying that underneath what to the ordinary scientific mind seems and is nonsense, such as denying the existence of matter, the reality of sickness, pain and death, and evidence given us by our senses, there is in it an element of truth, which the doctor of medicine ought to know and make daily use of. Their leaders claim they have a following of two million people, and they are not the ignorant people either, but as a rule, they are educated. They are increasing in number and influence. They have their expensive churches, which are well filled. They doubtless cure many cases that are real or imaginary, that are due to mental or psychological causes that the regular profession foolishly ignore. So also have others, as quacks, mental healers, relic dealers and holy waters, cured by the same agency of mental suggestion.

Let us now turn our attention for a few moments to the art side of our profession. We used to hear much of the art and science of medicine, or the practice of medicine as a profession and an art, etc. Apparently the art of healing has been overshadowed and swallowed up by the science of medicine. The old-time doctor had one advantage that the latter day educated doctor does not have, namely, the preceptor. The advantages and knowledge of the little arts of life to be gained by a young man just starting in practice from an intimate association with a refined, gentlemanly, and successful general practitioner cannot be overestimated. The following concrete illustrations of the point in question could

never have occurred had the doctors in question had such an example:

A well-meaning and well-read young doctor just starting in a village in New England lost an influential family, and so the whole village, and had to move on because he asked the countrified question, "Do your victuals hurt you?" Another doctor I know of lost business and standing because in the presence of a lady of refinement he took his thermometer from her mouth, wiped it on his doubtful pocket handkerchief and put it back in its case; still another bad break. A splendid country physician was called to attend a high-toned city woman. He put his hand upon her flesh and innocently remarked, "Why, you are as hot as a *skunk*, a'n't ye?" He did not mean anything by it, any more than the clergyman did in the following story: A miscellaneous company were playing cards in a camp in Maine, when a rough but worthy old fellow called a minister a d—— fool, because of a play he made. His companions later called him down and said he must apologize for it, which he promptly did after this fashion: "Say, elder, I hope you didn't mind what I said to ye last night. I didn't mean anything by it. I didn't mean nothing more by it than you do when you pray in the pulpit Sunday morning."

These doctors quoted, I hear you say, lacked the instincts of a gentleman. True, but many a brainy man has been handicapped by lacking them, because of heredity and early influence, and should have had them cultivated. It is attention to the little details of life that make success, yet I do not recall a lecture or a sentence in my medical course that touched upon the art of medicine. In my opinion, one of the most helpful books that has been written for doctors is Cathell's "The Physician Himself," and every young and old doctor ought to read it.

There is another side to this subject to which I ask your attention. It is that feature of it which links us with the great hustling world. I refer to the dollar side, or the practice of medicine from its business or bread-getting view. A physician is a genuine altruist. From a dollars and cents standpoint our profession is a monumental failure, for I need not attempt to prove to any company of doctors that very few men who rely on their practice alone ever become rich. I venture the assertion that there is no class of men who have invested so much in preparation and equipment, that get so small a return on their investment. This is in a small part his own fault, for a doctor is by common consent a poor business man.

Our profession occupies the unique position of having every man in it doing his best to destroy his own business, and in this respect we are succeeding to a remarkable degree. The work of our profession has decreased the death-rate in some places like London one half in the last two hundred years, has added many years to the average of human life, to say nothing of the saving of an inestimable amount of human suffering.

Every advance in medical science, every new discovery of the cause of disease, every new law in sanitary science, every advance in hygienic knowledge and right living, lessens the sum total of work for our profession to do. But in all these things the true physician rejoices, as he does to have his patient recover. But there are other influences at work that are not so noble and desirable. The Great Physician has said: "The laborer is worthy of his hire," but we are not getting it, and it is rapidly growing less.

I am no pessimist or alarmist, but from my point of view, if the present tendencies are not checked or changed, I shall be glad that the most active part of my professional work was done in the nineteenth instead of the twentieth century. This is an age of organization. Unionism and combinations are in the air, and gigantic trusts are being rapidly formed. The minister is respected for the sacredness of his calling, the lawyer and the judge are hedged about and protected by the sanctity of the law. There are all kinds and degrees of combinations, from that of the Northern Securities and Ship Combine to the union of the servants in the kitchen and the bootblack in the street. Capital is arrayed against labor, and labor is pitted against capital, and between these upper and lower millstones the unorganized are suffering severe and unnecessary hardships. Among the unorganized are the doctors. We have our medical societies, it is true, meet together quarterly, listen to a paper, pass a perfunctory vote of thanks for the very able, interesting and scholarly address (I think that is the ritual), then eat a good dinner, and rush back to our labor of love, wondering if those that stayed at home had swiped any of our few patients in our absence. There are 80,000 regular physicians in the United States to-day, and we are adding to that army 5,000 new recruits every year. The National Brotherhood of Boiler Makers requires that an apprentice shall work four years before he can be called a journeyman, while we have many medical schools which in one year of actual time will authorize by diploma any callow youth to rivet together the human boiler.

It has been computed that it takes at least 1,000 people to give a doctor a living, but we have at the present time one doctor to every 600 people. If each physician had the 600 people he would be lucky, but he hasn't. The abuse of the out-patient department of our hospitals is too well-known to need any words from me, and the abuse is with our help. It is an alarming and rapidly increasing evil, especially in our cities. It is estimated that now fully one-half of the population of New York City and Chicago are medical paupers in the hospital clinics. Another dangerous tendency is the formation for profit, often by laymen, of the so-called emergency hospitals, where any laboring man can be cared for, if injured, for one year for one dollar. Not only do the steamship lines and railroad lines have their surgeons, but there is a rapid increase in the number of and membership in social insurance organizations, such as the Hibernians, the For-

esters, United Hebrew Society, St. John Baptiste, Odd Fellows of the Manchester Unity, etc., where each member is cared for for one dollar per year.

Large contractors, manufacturers, mining companies are doing the same evil thing, and by the aid and consent of its agents and victims, the doctors. These are the days when the masses desire to get rich quick. Graft is also in the air, and it not only invades the government of cities and politicians, but even the professions are becoming tainted. Private hospitals and sanitariums, specialists, surgeons, and even nurses in some places offer a liberal commission on business brought them, and, I fear, could the actual amount of this nefarious business be made open and public, it would be a great shock to the moral sense of the profession as a whole.

Not only are the evils of counter-prescribing increasing, but the patent medicine evil is increasing, not only in quantity, but also in quality of business done. The elegance and combinations of modern large drug manufacturers now make it easy to any intelligent man or woman to remember the name of some favorite combination that their physician prescribed for them, and the next time it is wanted get it without asking the doctor's " If you please."

Our medical experts have come into such disrepute, as witnesses, because testifying for money instead of truth and justice, that an eminent English jurist has recently said, " There are three classes of liars, — liars, damned liars, and medical experts."

These are growing tendencies and evils on the business side of our work, not mentioning poor collections, dead beats, and bloodsuckers that yearly make it harder and harder for a conscientious doctor to live and support and educate a family; and they will continue to increase till the profession awakens and begins to assert some of its self-evident rights, and demand a fair treatment from the public. We are not only not paid by our patients, but more and more often, we are turned upon and abused most by those we have served best, aided and abetted by the shyster lawyer, who offers to take a case for malpractice for nothing if he fails, and divide the award if the doctor settles the case, and we have no redress. As illustrating this principle and tendency, I beg your indulgence in allowing me to quote a case and a chapter out of my own recent personal experience. In 1900 a carpenter was severely injured by a fall in my town and taken to the Framingham Hospital for treatment and repairs. He was found to have suffered a simple fracture of his left humerus, and a " T " fracture of his left tibia, into the ankle joint, with the left fibula dislocated and driven into the sole of the foot, with some other lesser injuries. At this time and for the next eleven days he was under the care of another physician. Both the arm and leg were put up in plaster-of-paris casts, well padded. An effort was made to hold the foot with other kinds of splints, but they would not hold it. By chance I happened in the accident room while the arm was being put up. I did not even know that the leg was broken. The toes were all left out as usual, and at no time showed evidence of undue pressure. There was but little pain in the foot, and but little morphia given. Eleven days after the accident, he asked to come under my care, because I was on duty at the hospital, and he could have my services free. This request was granted. On the fifth day of my service I removed the plaster and found a small dry slough, the size of a silver quarter, on the instep. I cared for him three weeks, when he went to his own home and physician. This slough gradually deepened until it destroyed the tendon of the tibialis-anticus muscle, and he was cared for in the Massachusetts General Hospital for many weeks. He lost in all some six months' time.

For the above case, the doctor who only gave the man ether, the doctor who took care of him the first eleven days, and myself, who cared for him the last twenty days he was in our hospital, were each of us sued for $10,000 apiece for malpractice; but the doctor who put on the cast was not sued, by mistake of identity.

For many years, because of this blackmail business, I have not kept my property in my own name, but what interest I might have had in my wife's property was tied up by this suit.

It was more than three years after this accident before the trial came off. In that interval, as is usual in such cases, hints were thrown out by the prosecution that a few hundred dollars to help the poor man would probably settle the suit. To add to my discomfiture, my two able and trusty lawyers advised me to settle the case if I could, saying it would cost me more to fight it than to settle it, and run the ever-present risk of being beaten before a jury. I am so constituted that I can throw good allopathic dollars into the stock market and see them depreciate into the thirtieth dilutions of homeopathic pennies, and whistle and grow fat, but to have my leg pulled for even a trade dollar makes my whole Anglo-Saxon spirit boil with righteous indignation, and therefore, perhaps with more stubbornness than sense, I refused the advice, and made a vow that I would sacrifice all my wife's relations before I would pay one cent in settlement, reaffirming in another form Otis's famous adage, " Millions for defence, but not one penny for tribute to a shyster lawyer."

The trial came, and with it the usual number of cheerful liars. Some of the testimony was rich. The plaintiff testified that he had such pain that the nurses gave him a Hypo. of Morph. every half hour for two days, whereupon one of Boston's famous surgeons reached over to me and said, " You do a land office business out in the Framingham Hospital, don't you? " Another amusing bit of testimony was when all the witnesses for the prosecution, especially the women, passed by the plaster cast on the arm, easily seen, and in serious procession all lifted the bed clothes to look at the leg, and all saw only one toe, the big toe, and that was always black.

But I must abbreviate my story. I am told that many large law firms think it necessary to have one solid man for influence and dignity, and another man to get business, like the Quaker's advice to his son, "Get business, honestly if possible, but get business." Such were apparently the prosecuting lawyers. It gives me pleasure to say publicly that the senior member of the plaintiff's lawyers, who had not said a word in the trial for the two days, and when not more than one half the witnesses for the defense had testified, came into court on the morning of the third day and moved that a verdict for the defense be given.

Two things helped to mitigate the annoyance of this case. First, the interest and loyalty of the doctors, some of whom gave generously of their time without thought of money, while yet others generously offered services that were not needed. Dr. M. H. Richardson, the man with a big heart, as well as a big mind and body, gave two days, as he said, for love and not for money. Dr. Mixter heroically sat out a whole day when he ought to have been in bed because he was sick. Dr. Bottomley of Boston, Dr. Hoitt of Marlboro, and Dr. Wood of Waltham all gave two days for the love of right.

Second, because this was a hospital case, both my lawyers, Ex. Dist. Attorney P. H. Cooney of Natick and Ex-Representative John M. Merriam of Framingham, both able and busy men, gave probably a week each, and both refused all money consideration. My money expense, therefore, consisted only of railroad fares and banqueting the lawyers, doctors and witnesses at the hotels and restaurants of Cambridge, and those of you who know of them don't need to have that joke labeled.

My story of this case would not be complete were I not to tell what to me is a delicate and sad part of it. When I told my case to my senior counsel, he at once replied, "There is some doctor at the bottom of this. There always is." I replied, "There can't be, for there is no reason for there being one." I can understand how the family physician of this injured man would sympathize with him, — he ought to. He may have tried to discourage a suit, though I have evidence to the contrary. I can easily forgive him for taking the witness stand against me, because he would be obliged to when summoned, but I couldn't understand then, and I can't now, after six months of sober thought, how any physician, with any true professional spirit, and especially an honored member of this society, would give over to the prosecution a personal and confidential letter I wrote him as a favor, to be used against me, after three years' time, and while upon the witness stand, when lawyers say he was under no obligation to do so. This courteous letter of mine was never even acknowledged, and I have never received any note of interest or sympathy in any way since from him.

Another very marked and popular tendency of the present day practice of medicine is toward specialism. Unfortunately for a clear discussion of this subject, the term is used loosely and differently. It has a catchy and high sounding tone to it that covers a multitude of shortcomings. It is a fetish which the popular fancy just now worships. Nothing that I know of will so quickly satisfy an uneasy patient, and the meddlesome interest of perhaps well-intentioned neighbors, as to say to a family, "Well, this is so rare and unusual a case that we will refer it to the final and supreme court of medical knowledge, and have a specialist from the city come out."

This has a twofold attraction. He is not only a specialist, but he is from the city. Did you ever hear of a specialist from the country being called? It would be a paradox. It is a very common idea among the city as well as the country minds that a residence and practice within the city's corporate limits carries with it a superior knowledge and *vice versa*, and that because a man chooses to live where he can enjoy driving through the woods and the green fields, and see and hear some other bird sing beside the chattering, quarrelsome and contemptible English sparrow, he is in consequence inferior to his city brother.

But to return to my specialist. He comes out with the air of a conqueror, and the paraphernalia of his peculiar specialty. He looks wise, and at once gives the impression that at last we have found a man that knows. He asks questions, both relevant and irrelevant. He uses big words that have been coined to express conditions that we do not understand, but sound expressive. He gives a big name to the disease or condition, but when he comes to suggesting a big medicine to fit and cure the big name, he at once comes into the same class with the countryman. He, however, gives some directions which the home doctor is glad to carry out, for he is at his wit's end, and ready and glad to try any new thing. The patient's mind has taken on new hope, for he had seen a specialist from the city, but physically he remains the same, and, after a few days, finds himself in the same old condition. I am reminded of the apt and quaint way in which that prince of men and teachers, and under whose instruction it was my happy fortune to have been, Dr. Oliver Wendell Holmes, put it, when he said of a man who consulted many specialists, and finally died just the same, that he raised the question whether it would not have been just as well and a good deal cheaper if the patient had *not* got well under his family physician at home, as under the city specialists. It is a law of economics that the supply will equal the demand. Create a demand of any kind, and there will be a consequent and necessary supply. Specialism is in the air. It is everywhere and creating a universal demand. We see it in the one hundred and forty different religious sects with their varied beliefs and teachings. We see it rapidly developing in the legal profession. We see it running wild in our system of education, and especially in our higher institutions of learning, where electives have gone so far as to already alarm its advocates. We see it in all lines of

business. We see it in manufactures, where the work has become so divided and subdivided that the part of each person has become so small a part of the finished product, that the workman becomes practically a machine or automaton himself and by that much cramped in his development. Well do I remember the little boot and shoe shop that was so common all over New England twenty-five to fifty years ago, where each man made the whole boot or shoe and was a master workman, knowing the business from A to Z. If necessary, I could name other lines of specialism.

In the profession of medicine there has been the same tendency and the process is still going on. In a delightful book recently published, and written by Dr. Mumford, one of our bright young Boston surgeons, entitled "A Narrative of Medicine in America," he devotes his closing chapter to tendencies in medicine, and among them he speaks of specialists. To learn how many were becoming general practitioners and how many were specialists, so-called, he sent a series of questions to the graduates of Harvard Medical School, in the ten years from 1892 to 1901, which were in number 820 men. Of this 820 graduates questioned, 487 responded, or nearly two thirds. From the replies, several very interesting facts were learned. First, only 191 out of 487 had settled in large cities of 100,000 people or more; 229 men, or nearly one half, had settled in small cities of from 10,000 to 100,000 people, while only 38 were in places of less than 10,000 inhabitants, or country practice. Of these 487 doctors who responded, 96 are pure specialists, or about one in every five men, and four out of five classified themselves as general practitioners. Of the general practitioner, 99 combine some specialty with their general practice, and 77 of them intend and expect some day to abandon general practice for a specialty. If this intention is carried out, and none of the specialists get discouraged or change for other reasons to general practice, this would make more than one third of these graduates of ten years, specialists. Of the 487 reporting, only 202 are and expect to be "Simon pure" general practitioners, or less than one half.

Another surprise to me was the fact that only two out of this whole number stated that they had been general practitioners and had now become specialists. Still another surprise was the number of different specialties returned, there being thirty-three in all. With the present tendency, it is only fair to expect that this number will be still further enlarged and subdivided. Within my day I have seen them rapidly increase.

An interesting discussion has been going on of late, as to whether or not this increased specialism did not eventually result in the final extinction of that once upon a time highly appreciated species, called "the beloved family physician." There are those who would make of him only a person like that of a doorkeeper of the large clinic, a man who sorts out the kind of trouble and then tells them what room to go to for special treatment.

As an illustration of this tendency, but I imagine an unusual case, I quote from an address given by one of Boston's eminent lawyers, Mr. Moorfield Storey, before the Harvard Medical Alumni Association recently, in which he said that within one year he had employed in his family twenty-three different doctors. In this connection I raise the query, Did either one of these twenty-three different doctors know thoroughly any one member of that family, so as to treat him intelligently as a unit, or a harmonious or inharmonious whole, or did each one, like the modern shoemaker, attempt to repair some small individual part of this intricate machine, whose function may have been thrown out of harmony or health by some reflex influence, arising in some other part of the body, to that individual specialist a hidden book?

Is there such a thing as knowing one's constitution, and has every individual a personal equation, which an intimate, experimental, personal knowledge, by a family physician extending through many years, would enable him to treat and care for more thoroughly and successfully, than the new man or any number of special knowledge men? My experience teaches me that this is so. Lest my position be misunderstood, and I get the credit of being opposed to specialism and specialists, I shall risk a little more personal history, and confess that I, too, pose as a quasi-specialist. After fifteen years of general practice in a large country town and village, I found myself interested in special lines of my work, and I spent more than a year in Boston, New York and the medical centers of Europe in preparing myself for those special lines of work. This study was a perfect delight and I am glad I made it, for it not only gave me new light, but the breathing spell gave me a new lease of life. Because of real estate anchors and a too strong love of old friends, I returned to the place of my general practice, hoping in time to devote myself entirely to the special work I enjoyed most, and drop the hard parts of a general practice.

In the past eight years I have demonstrated the following points to my own satisfaction: First, that it is very difficult and practically an impossible thing for a general practitioner to drop his general practice, while he remains in a place where he has become thoroughly known and established as such. Second, that so long as a person does any general practice, he need not expect to be acknowledged a specialist or given work as such by his brother practitioners to any extent, for fear of losing patients. On this point I find no fault or make any harsh criticism. It is perfectly natural. Third, that when one makes any claim to specialism, a certain proportion of the people think that from lack of interest or ability he becomes less valuable as a general practitioner. Fourth, that specialism and general practice are not incompatible or undesirable, either from a professional or monetary or enjoyment point of view, but rather to the contrary. Fifth, that having learned the limitations of the specialists, I have a peace of

mind that the world cannot give or take away. Sixth, that with the higher requirement now insisted upon by our best schools in the four years' course, and the critical work now done in small sections along special lines, every man allowed a degree of M.D. should be a specialist along general lines in nine out of every ten cases he sees, and be able to tell when, because of his own limitations, to send the tenth case to some one with superior knowledge and skill, who can do better for him than he can. Seventh, I am firmly convinced that the family physician has a work and a place that no amount of specialism ever can or should destroy. That at the present he is under a cloud and not justly appreciated, but with the development of humanitarian tendencies so noticeable at the present time, he will again be recognized and appreciated as a potent factor in the world's betterment and advancement.

Having given you what have seemed to me some of the unfortunate tendencies of our noble profession, you will probably ask me for my remedy. I offer the following suggestions as a tonic:

First, a better *esprit de corp*, and less foolish jealousies in our ranks. Second, a cultivation of a more businesslike profession, putting a proper value on our own services, sending bills and collecting them. Third, a better organization, in simple self-protection. Fourth, the discouragement of the free clinic for those able to pay, and the employment of society doctors. Fifth, the joining of a physician's defence alliance, and fighting every case of malpractice instead of compromising it. Sixth, the improvement in the quality, and lessening the number in our profession when possible. Seventh, taking greater interest and active part in legislation that affects us as a profession. Eighth, by enlarging our medical vision beyond material agencies. Ninth, by an increased interest in national organizations, and co-operation in regard to moral betterments such as divorce laws, food and drug adulterations, sanitation, national quarantine regulations, etc. Tenth, uniformity of requirements for a degree in different medical schools, and in examinations for permission to practice in different states, with reciprocity between such states in these certificates, and other similar laws.

I cannot better close my paper than by the following quotation from an editorial in the *Christian Register:*

THE FAMILY PHYSICIAN.

"This is such a day of specialties that comparatively few can ever enter into the dear old relation that existed formerly between physician and family. Heart secrets and sufferings that the minister could not extract from burdened souls were poured into the trustworthy ear of the good doctor who ministered to soul quite as much as to body. His breast was the safe repository of every man, woman and child in the parish who needed his confidence, and to no other human being did he ever betray these confidences. When such a man enters the sick room the burden of anxiety falls from the mother's heart; her child is safe so long as he is there. It seems as though he had power to banish the death angel; or if, indeed, that sad messenger must come, the physician becomes the sympathetic friend who gives strength to bear the sorrow.

"There is no man in the community who has more love and respect than the good physician. As a rule, physicians are more permanent residents than ministers, since short pastorates are now the fashion, so that the pastor must give up to the doctor the place of honor which he once held when he was the curé of two or three successive generations in the same parish. One asks with sadness as the poets pass away, Who is going to sing the songs of the future? When the great men die we ask, Where are they who are to be the great men of the days to come? And so, when we see the family doctor going his rounds, faithful, generous, devoted, and daily growing more wise, threading his way through crowded streets that were pasture-land when he began his practice forty years ago, we ask with a pang at our hearts, Who can ever take the place of the beloved physician? Long may he be spared! And may many of the young men who are now seeking that profession for 'what there is in it' find that the noblest thing in it is the opportunity that it gives for devotion and self-sacrifice, for winning love and honor, and for saving men, heart and soul, as well as body. No profession requires more of a man — fidelity, purity, wisdom, patience, hard work, sleepless nights, weary days; but no profession brings richer rewards or sweeter benedictions."

Original Article.

EXAMINATION OF PLEURAL FLUIDS WITH REFERENCE TO THEIR ETIOLOGY AND DIAGNOSTIC VALUE.*

BY PERCY MUSGRAVE, M.D., BOSTON.

THE examination of pleural fluids for many years has furnished us with little valuable data upon which to base a positive or even probable diagnosis of the underlying cause of the effusion. To be sure the specific gravity and the amount of albumin have, in most instances, enabled us to differentiate between the exudates and transudates, and in few cases masses of the so-called cancer cells have been of positive diagnostic value.

In the last three years many investigators in Europe have done a large amount of work with reference to determining the cause of these effusions, and two new and valuable methods of investigation have been published.

In 1900 Widal and Ravaut [1] published the results of their researches based upon the differential enumeration of the white blood corpuscles and endothelial cells found in the sediments of

* Read before The Massachusetts Medical Society, June 7, 1904.
[1] Widal and Ravaut. Compt. Rend. de la Soc. de Biol. de Paris, 1900, p. 648.

serous fluids, and as a result have formulated the following laws, or so-called cytological formulae:

1. A predominance of lymphocytes means a tubercular effusion.

2. A predominance of polynuclear leucocytes means an effusion of an acute infectious origin.

3. A large number of endothelial cells, occurring especially in sheets or plaques, means a mechanical effusion or transudate.

They also divide tuberculous pleurisy into two classes. The primary form, in which there are no discoverable lesions of the lungs, and the secondary form resulting from an underlying tuberculous lung focus.

In the secondary variety the lymphocytic formula, as seen in the primary form, is usually not found, but instead the sediment is almost entirely composed of necrotic cells and detritus. Of the distinguishable cells a large proportion may be polynuclear. This difference is probably due to a mixed infection

Of the acute infectious varieties they note those due to the pneumococcus, streptococcus and staphylococcus In the pneumococcus variety they described the occurrence of considerable numbers of large cells having phagocytic properties. In the streptococcus variety these cells are comparatively few in number and the percentage of polynuclear leucocytes is greater.

These formulæ have been extensively investigated by numerous observers, especially in France, and, to a lesser extent, in Germany, and have in the main been found correct. Certain modifications, however, must be taken into consideration. The chief of these modifications which has been pointed out especially by Naunyn [2] is, that lymphocytes may also predominate in transudates of long standing or near the end of an acute infectious case where the process is subsiding or where the infection is a very mild one. The specific gravity and the amount of albumin aid us in eliminating the first mentioned of these conditions, and the clinical evidence usually gives a clew to the nature of the process in the second condition. Both of these conditions are rarely met with.

In the first week or ten days of a tuberculous effusion polynuclear elements may predominate, but these rapidly disappear and give place to a purely lymphocytic formula.

The phagocytic cells mentioned above as occurring especially in the cases of pneumococcus origin are of very large diameter as compared with the other elements occurring in the sediment, and I have frequently found that they measure as much as twenty microns. These cells frequently contain partly digested polynuclear and other cellular elements, which can easily be seen included in their protoplasm. Their occurrence in large or increasing numbers is usually a good prognostic sign, and their absence, together with the presence of bacteria, is usually a warning of approaching empyema.

From the observations which I have been able to make, the presence of polynuclears in a proportion of over 90% and the presence of bacteria in most cases precedes an empyema by only a few days.

Little need be said of the formula for the transudates except that the diagnosis is occasionally complicated by the presence of a considerable amount of blood which raises the specific gravity and the amount of albumin. This blood is usually accidental.

In addition to these above three classes of fluids we have the cancerous cases. These are difficult to diagnose, since the majority of pathologists agree, I think, in saying that it is difficult to differentiate the so-called cancer cells from endothelium, unless actual pieces of the cancerous tissue can be isolated. The iodine reaction (showing glycogenic degeneration) was thought at one time to be suggestive of the cancer cells, but this reaction is very commonly seen in the endothelial cells of simple transudates and in other conditions where endothelium is found.

The few cases of cancer that I have been able to study have shown a high specific gravity, 1,018 or over, and an albumin content of over 1.5%. The sediment has shown many more endothelial cells than are found in the tuberculous cases and these cells are often found in plaques. This is very rare in tuberculosis. There is usually a much larger number of lymphocytes proportionally than in the simple transudates.

In addition to the above method of investigating pleural fluids, to which the writers have given the name cyto-diagnosis, Jousset [3] has published a new procedure for the detection of tubercle bacilli in these fluids, to which he has given the name of inoscopy and which is of value in some cases.

The technic of cyto-diagnosis is as follows:

The fluid should be drawn with the usual aseptic precautions into sterilized flasks or tubes. If it is already clotted when received for examination, it should be shaken and stirred with a glass rod until the clot is thoroughly contracted and the clot, or all clots of large size, should be removed. This is necessary because some of the cellular elements are entangled in the fibrinous meshes and by contraction of the clot are set free.

Widal and Ravaut accomplished the process of defibrination by placing sterilized glass pearls in the flask and shaking the fluid thoroughly. This I do not believe is essential for an accurate differential estimate of the cellular elements.

The fluid is then placed in centrifuge tubes and centrifugalized for five minutes at least.

Decant the supernatant fluid gently at first, and when only a small amount remains invert the tube for a few seconds. A few drops will adhere to the side.

[2] Naunyn. Uber Cyto-diagnostik der Pleuraexsudate. Deutsche Med. Wchnschr. Leipz. u. Berlin, 1903, Apr. 30, 1903. xxix, Ver. Biel., p. 140.

[3] Jousset. Soc. Med. des Hop. 9 Jan., 1903. Sem. Med. No. 3, 1903, p. 22.

With a small platinum loop stir the sediment thoroughly, rubbing the sides of the glass to remove adherent portions. When the sediment is thoroughly mixed with the few drops of fluid remaining after decantation, remove a drop of the mixture with the platinum loop and make a cover-slip smear. Allow this to dry spontaneously or by gently heating the preparation. (Heating at the boiling-point will spoil the preparation.)

Many methods of fixing and staining these preparations have been used by the various investigators. Alcohol, and ether, chloroform vapor, and osmic acid have been used as fixative agents. Ehrlich's triple stain, hemotoxylin and eosin, methylene blue and eosin, Loeffler's blue, and a great variety of other stains have been employed.

Some writers have maintained that careful differential staining was not essential, but from my observations I cannot agree with those holding these views, for the reason that careful differential staining of the protoplasm and granules of the polynuclear elements is essential, since the nuclei of these elements are often globular when the cell is degenerated, and they may be mistaken for lymphocytes.

The method of staining which has given the best results in my hands is practiced as follows: Cover the preparation with a staining fluid composed [4] of

Wright's blood-stain,	3 parts.
Pure methyl-alcohol,	1 part.

Allow this mixture to remain on the preparation twenty to forty-five seconds, then dilute it with eight or ten drops of water, and allow it to stand one or two minutes.

Wash very gently, preferably by flooding the slide with a dropper. Do this four or five times, allowing the water to remain on the slide a few seconds each time. Vigorous or forcible washing will destroy the film and spoil the preparation.

Dry the preparation by holding it between the thumb and forefinger and waving it through the Bunsen or alcohol flame. Do not attempt to blot the preparation or heat it above the temperature which the fingers will bear.

Mount in xylol-balsam and examine with an oil-immersion lens.

Inoscopy is practiced as follows:

1. The fluid should be drawn with aseptic precautions into sterilized flasks (Ehrlenmeyer flasks preferably) and at least 100 cc. should be taken, although results may sometimes be obtained with much smaller amounts. Allow the fluid thus taken to clot.

2. Shake the fluid gently to contract the clot as much as possible, and then wash it on a piece of sterile linen or fine gauze wrapped over the end of a funnel, until all the serum is washed away.

3. Remove the clot or clots with a sterile spatula, and place it in a small flask with sufficient of the following fluid to digest it:

Pepsin,	2 gm.
Pure glycerin, }	each, 10 cc.
Strong HCl, }	
Sodium fluoride,	3 gm.
Distilled water,	1000 cc.

The amount of this fluid necessary will vary, of course, with the size of the clot to be digested, but 20 or 30 cc. is sufficient in most cases. A freshly prepared pepsin — HCl solution — apparently serves as well as the above fluid, but will not keep on standing as the above fluid does.

4. Place the above preparation in the incubator or oven until the clot is digested. A temperature of 37 C. for two or three hours will suffice but the time is shortened if kept at a temperature of 50 C.

5. When the clot has disappeared, pour the mixture into centrifuge tubes and centrifugalize for five or ten minutes. Decant the supernatant fluid as described under cyto-diagnosis.

6. Make a cover-slip preparation and stain it for tubercle bacilli. Care, however, should be taken not to decolorize too long — one half to three quarters of a minute with Gabbet's solution is sufficient. Dry and mount.

The majority of the bacilli found by this method are shorter and broader, as a rule, than the tubercle bacilli usually seen in sputum, and some are paler red, but all forms occur. These bacilli may occur singly or in groups. The largest part of the sediment consists of undigested nuclei and a small amount of detritus.

Chiefly through the courtesy of the Visiting and Out-Patient Staff of the Massachusetts General Hospital I have been enabled to make systematic examinations upon seventy-two cases of serous fluids withdrawn from the chest, and the remarks and conclusions which follow are derived from the study of these cases with reference to their clinical history, chemical and microscopical examination of the fluids, and from animal inoculations and cultures in a large number of the cases.

For the sake of convenience, I shall divide these cases into four classes according to the diagnoses justified by the examination of the fluids:

Class 1. The Tuberculous cases.
Class 2. Acute Infectious cases.
Class 3. Mechanical Effusions or Transudates.
Class 4. Cancerous cases.

TUBERCULOUS CASES.

The largest number of cases examined must be classified under the first heading. Of these there are fifty-one. To follow out the scheme of Widal and Ravaut,[5] this class must be further sub-divided into the primary and secondary tuberculous cases, namely, those cases in which the sputum is negative, and there are no demonstrable lung lesions, will be classified as primary; those cases in which the examination of the spu-

[4] Wright, J. H. The Journal of Medical Research, 1902, Vol. II., pp. 138–144.

[5] Widal and Ravaut. *Loc. cit.*

tum shows tubercle bacilli will be classified as the secondary cases. This is by no means a strictly anatomical classification, but an arbitrary one used for the sake of convenience. Before dividing them into these two sub-classifications, I shall speak of the tuberculous cases as a whole. Out of fifty-one cases, twenty-eight were positively proved to be of tuberculous origin, 54.5%. They were proved by one or more of the following methods:

Animal inoculation.
Presence of tubercle bacilli in the sputum.
Operation.
Inoscopy.

Seventeen cases, 33%, in this series gave positive results when inoculated into guinea pigs, producing unmistakable anatomical lesions in these animals from one or more of which in every case bacilli were demonstrated by cover-slip preparations. In thirty-three cases the animal inoculated showed no evidence of tuberculosis.

Inoscopy was positive in ten, 45.4%, out of twenty-two cases in which examinations by this means was possible. This method was not applied to cases examined before Sept. 4, 1903, but since then it has been brought into use on all cases in which there was sufficient coagulum. In a considerable number of the cases this was so small as to exclude the possibility of doing inoscopy, and I have not yet been able to find any practical and simple method of causing these fluids to clot.

The bacilli found were, in the majority of cases, short forms resembling the tubercle bacillus grown on culture media, and in some instances resembling the familiar form of tubercle bacillus seen in sputum.

In two cases bacilli were found both by inoscopy and in the lesions in guinea pigs.

In five cases the tubercle bacillus was found in sputum; in two of these animals inoculation was positive, and in two negative, and in one case no other tests were applied.

One case was proved by the tuberculin test and subsequent operation for tubercular peritonitis.

As I have just shown, forty-six of these cases come under the heading of primary tuberculous pleurisy and five under the heading of the secondary form. Twenty-three, 50% of these cases, as I have shown, were certainly tuberculous. Of these, the differential counts of the white cells in the sediment showed a marked predominence of lymphocytes in twenty-two of the twenty-three cases. In one case necrotic changes in the sediment rendered the differential estimation of the cells impossible. In other words, the lymphocytic formula as described by Widal was found in twenty-two out of the twenty-three cases; in one case the diagnosis which was indicated by the sediment would have been secondary tuberculous pleurisy but no bacilli were found in the sputum. Out of the twenty-three unproved cases of this series twenty-two showed an unmistakable predominence of lymphocytes.

The question now naturally arises, What evidence have we that 50% of this series is tuberculous, seeing that we have been unable to prove it? The clinical history in both the proved and the unproved cases is identical, namely, that the majority show an insidious onset with pain in the chest, slight cough, with or without sputum, and gradually increasing dyspnea and anorexia. An appreciable elevation of the temperature may or may not be present in any of these cases. The appearance of the patient does not give us any differentiating clew. In other words, the clinical picture is the same in both series.

Of the twenty-three unproved cases two can be excluded as in all probability not tubercular by means of the clinical history. One was an unmistakable pneumonia followed by a pleuritic effusion; the other was a case of myocarditis, and from the specific gravity was, without much doubt, a case of transudate; in other words, the examination of the sediment led us to faulty conclusions. (Cases 51 and 50.) In one case there was a history of trauma and, although the specific gravity and albumin were both high and the sediment showed a marked predominence of lymphocytes, the question arises if this does not fall into the class of mild acute infections which I have previously mentioned as a source of error. (Case 48.)

Another case, coming on eight days after labor with sudden onset, suggests the possibility that this case also may be one of the same nature. (Case 41.)

It is also fair to exclude a fifth case where pleural effusion arose in the course of a lymphatic leukemia, since the number of lymphocytes in the blood in this case would strongly suggest that their presence in the pleural fluid was of blood origin. The white count was 711,900, the differential count showing five hundred lymphocytes in a count of five hundred cells. (Case 39.)

Of the remaining eighteen cases the history in four suggests a tuberculous origin. The reasons for the failure to obtain proofs in these cases, although theoretical, are certainly plausible by analogy.

Out of fifty animal inoculations made with the fluid from cases showing the so-called tuberculous formulæ, even including the cases which we have shown were probably not tuberculous, only 33% appeared positive, but we have seen that by inoscopy we have been able to find bacilli in ten cases, only two of which gave positive results in the pig; in other words, where the bacilli were found by inoscopy the animal gave negative results. This suggests that in many of these cases the bacilli have lost their virulence for animals. This is also rendered more probable from the fact that I have several times seen organism within the cells of cover-slip preparations made from the sediment which would not grow on culture media.

As further illustrating the difficulty of proving these cases in one of the series of proved cases (Case No. 2) inoculations of three animals from

three successive tappings in November failed to give any positive results, but, although there was no change in the character of the fluid or in the condition of the patient, except for reaccumulation of fluid, an animal inoculated in May gave positive results, and another case (Case No. 14) in which three successive inoculations occurring within three weeks of each other were made from the fluid drawn from the same patient, the first animal inoculated was positive and the other two negative. Another case (Case No. 27), reacting to tuberculin and showing at operation tubercular peritonitis, gave negative results when inoculated into a guinea pig.

In Barjone and Cade's [6] series of cases it was not an unusual experience to have only one out of taree or four animals inoculated respond.

This class of cases, namely, the so-called primary tuberculous cases, is the one which has given rise to so much discussion for the last twenty years. It was formerly attributed to taking cold, so-called "Pleurisy *a Frigore*," but the investigations of the French school, also those of Naunyn,[7] Litton and Wolff [8] have shown us that at least the great majority of cases are probably tuberculous. To Landouzy,[9] Le Damany,[10] and Widal and Ravaut we are indebted more than to any others for the interest aroused in the investigation of this problem, and for pointing out valuable methods of investigation.

With regard to the cases of secondary tuberculosis, little need be said, as, with one exception, they all show the formula described by Widal.

One case, however, did not show the necrotic, broken-down sediment, but an evident lymphocytosis; this, however, is not particularly significant since it would have led to the diagnosis of tuberculosis in any case. It is in this class of cases that the examination of the fluid is of the least diagnostic value since the diagnosis can be made in any event from the sputum.

It has been possible, however, in two of this series of cases to predict the finding of tubercle bacilli in the sputum, which subsequently occurred.

In one of these cases, reported in a former article, although the examination of fluid was that of a hydro-pneumothorax, or secondary tuberculosis, no proof of its being tuberculous could be found at that time, but subsequently, the patient re-entering the hospital, bacilli were found in the sputum.

ACUTE INFECTIOUS CASES.

There are twelve of these cases, six resulting in the course of an acute croupous pneumonia, one from infarction of the lung, with subsequent infection with the pneumococcus, three started from unknown sources, one from trauma and one from abscess of the liver infecting the pleura without rupturing into it.

In six there was no growth on culture media, two showed pneumococcus, two streptococcus, one staphylococcus, and in one no culture was taken.

In seven of the cases organisms were found on the cover-slip, usually few in number.

Five of these cases are of especial interest. In one (Case No. 63) where the diagnosis of an acute infection was established against a clinical probability of its being tuberculous, the examination was of great aid in determining whether or not an operation should be done for an abscess of the liver.

In one case (Case No. 53) it was possible to predict an empyema, which subsequently followed.

In two cases (Cases No. 60 and No. 61), although the fluids were serous, streptococci occurring on the cover-slip determined the advisability of immediate operations.

In one case (Case No. 52) in which the clinical diagnosis was endocarditis, and from that diagnosis it seemed most probable that the fluid was a transudate, examination showed an acute infectious process, and subsequently at the autopsy it was shown that the effusion was due to infarction of the lung which had been invaded by pneumococci with resulting consolidation. The sediments in these cases showed a predominence of polynuclear leucocytes.

TRANSUDATES.

Of five cases of simple transudate four appeared in the course of cardiac disease and one in the course of nephritis.

One of these cases (Case No. 67) illustrates the probable accidental occurrence of blood which at the second tapping was not present, but instead the fluid had the characteristics of the typical transudate.

(To be continued.)

Clinical Department.

SUB-GLOTTIC TUBERCULAR LESIONS OF THE LARYNX.*

BY THOMAS AMORY DE BLOIS, M.D., BOSTON.

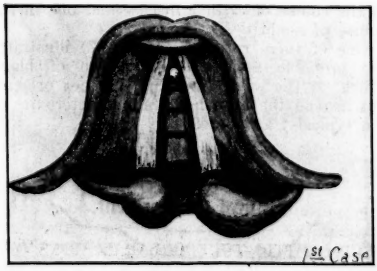
It has always been a question for argument as to whether tuberculosis is ever primary in the larynx, and any instances which throw even a feeble light on this subject seem to be worthy of being reported.

There have been, of course, numerous cases of apparent primary tubercular lesions of the parenchyma of the larynx, where the absence of physical signs in the lungs and the constitutional disturbance would seem to indicate that the larynx was the point of first infection, but these two cases which I report were already well advanced in lung disease before the subglottic

* Read at the annual meeting of the American Laryngological Association, June, 1904.

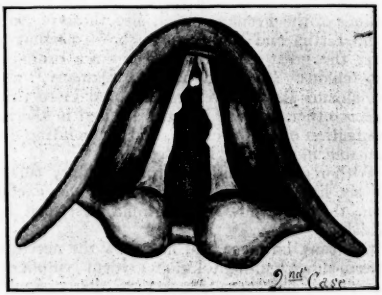
space became involved. Besides this, tubercle bacilli were found in the sputa on the first examination. I have never known tubercle bacilli to be found where there were no physical signs. In sections of a tubercular larynx, even where there is deep ulceration, demonstration of the presence of bacilli is far from easy. My cases were both from the Boston City Hospital.

My first case was a young Irish lad, Hugh W., and his history and appearance are best stated in the words of the Medical Department, to which he was referred. His age was twenty-three, and he was a butler by occupation. As to his family history, his father and mother are alive and in good health; four brothers and three sisters are in the same condition. One brother died of diphtheria, and two others of some unknown cause in infancy. The patient had measles when a child, pneumonia at eleven years, also an abscess in the throat. He never had venereal nor rheumatic disease and does not use alcohol nor tobacco. He has had a cough since July, 1903. The sputum is yellow; there is persistent cough. He had sore throat for three weeks. The dyspnea was so severe as to cause him to give up work. His appetite was fair. He has lost nineteen pounds of weight. He weighs one hundred and sixteen and a half pounds. His physical examination shows him to be poorly developed and poorly nourished. Heart is systolic at apex. Apex beat visible and palpable in fourth interspace inside nipple line. Right border in line with right border of sternum. The lungs show dullness in left apex, to second rib, to right apex. There were rales in both apices, and front and back, and in base of left lung (fine musical), occasional squeaky rales heard above spine of scapula on the right. Tubercle bacilli were present (Feb. 26). On laryngeal examination the larynx was observed to be somewhat hyperemic, the voice was not hoarse, the arytenoid cartilages were not much enlarged, the vocal cords were somewhat reddened, but the edges were sharp and smooth. Between the cords and in the region of the anterior commissure could be seen a round, red swelling situated about an inch subglottic. This first examination was before the physical examination was made, and was about the middle of February. I believed this to be a subglottic abscess, and so entered it on the records.



Two days after this the supposed abscess had either ruptured or broken down and presented the appearance of a slightly raised circular swelling with a white ulcerated centre. The rest of the larynx did not show the evidences of tuberculosis in a marked degree. Suspecting the tubercular origin of the lesion the patient was sent to the medical department, and the before-mentioned report was received. A specimen of sputa was furnished the pathological department and a report of the presence of "T. B." was returned. Under constant local applications of lactic acid, together with the use, internally, of "Creosotal" the subglottic ulcer slowly healed, the patient gained weight, and as the laryngeal condition did not interfere with deglutition, there seemed no reason why this patient should not secure an arrest of the tuberculous process in the larynx. From the advancing disease in the lungs, however, this patient went down rapidly, although the throat complications did not return.

My second case came to the City Hospital clinic within a few days after my first, and so much did the conditions of the second larynx resemble the first, that I might have mistaken the two patients (except that the second was a Swede and the first an Irishman). Karl H. was aged twenty-four years and was born in Sweden; was an upholsterer by trade. A little over three months ago was hoarse and came to see what the matter was. The vocal cords and arytenoids were somewhat swollen and slightly reddened. Below the anterior commissure, exactly in the same position as the first case, was a similar open ulcer. The patient was sent to the medical department for physical examination, and the following report returned:



Karl H., aged twenty-four, Swede, upholsterer. Father and mother are living and well. Two sisters and four brothers are living and well. There is no lung trouble in the family. He has always been well; the first time he ever went to a doctor was to the Throat Department for his hoarseness. About three years ago he had gonorrhea which was cured in three weeks. He uses no tobacco nor alcohol; once in a while uses a little snuff. Bowels are regular, he sleeps well, his appetite is good. Two months ago he began to feel lazy, and not so strong. He commenced to be slightly hoarse nine weeks ago, and this brought him to the hospital a short time ago. He expectorates about a tablespoonful morning and night; the color is green and white, and thick. He coughs mornings and evenings, and sometimes during the day. He sweats very little, if any, and sleeps well at night. No pain in throat at any time; no pain anywhere. He does not feel so strong now. He thinks he has lost seven and a half pounds in past one and a half years. Now weighs one hundred and thirty-five pounds. Does not know what his best weight was. His color is good, tongue coated, slightly cyanotic. Heart negative, save for soft systolic at pulmonary area. *Lungs:* Dullness with moist rales at right apex. Abdomen and legs

negative. This case retrograded very rapidly; by the time I made my sketch, the ulceration had crept upwards and involved the edges of the cords. Aphonia came on, deglutition became difficult, and death came a little quicker than in the first case where the larynx did not become ulcerated. It is rarely that ulceration below the vocal cords is seen primarily.

TECHNIQUE OF GASTRO-ENTEROSTOMY.[1]

SPECIAL PREPARATION OF PATIENT FOR OPERATIONS ON THE STOMACH.

BY C. A. PORTER, M.D., BOSTON.

In emergencies such as perforation, or acute gastric hemorrhage, no previous preparation of the patient can be made. It must be borne in mind, however, that, if possible, the rectum should be thoroughly emptied, previous to or during anesthesia, in order that subsequent enemata may be given.

In operations of election, attempts may be made, first, to improve the nutrition and anemia; second, to empty the stomach, and to render it and the upper intestine as free from bacteria as possible; third, to minimize shock.

(1) Improvement of nutrition and anemia. On carefully reviewing the various and varying opinions of authorities on the value of rectal feeding, I have concluded that it is overestimated. I am not speaking of those cases in which, from the necessity of resting an ulcerated stomach, the rectum is used because the stomach cannot be, but of protracted attempts to improve the nutrition, previous to operation, by nutritive enemata. It is doubtful if a patient at rest can absorb from the rectum more than two thirds to three fourths of the amount of nourishment to maintain tissue equilibrium. Fluids are, of course, readily absorbed. It is more than likely that many reported cases of weight sustained for long periods give an erroneous idea that the tissues in contradistinction to the fluid portion of the body have not suffered. In cases which have received no proper medical treatment, and in those who have pyloric obstruction and starvation, it is a nice question of judgment how much preliminary treatment should be given. In the cachectic, especially in cases of stasis, attempts should be made for a week or ten days, by daily or twice daily stomach lavage, to thoroughly cleanse that organ. Easily digested foods, giving small residue, may be given at short intervals, such as egg white, beef juice, thin soups, peptonoids, alcohol, sugar solution, etc. The character of the fluid which is used in washing is of secondary importance, as the effect is almost entirely mechanical. Warm saline, bicarbonate of soda, or boracic acid solution, are to be chiefly recommended. The value of antiseptics, such as resorcin, carbolic acid, beta-naphthol, etc., is doubtful and certainly much inferior to mechanical cleansing. In general, not more than a week should be given up to such preliminary treatment, and often a period of three or four days will accomplish all that can be done. Rectal feeding in these cases may be given with two objects, — to supplement absorption by the stomach, or to accustom the rectum to enemata, which will be used subsequent to operation. The amount, as a rule, should not exceed eight to ten ounces, three times in twenty-four hours. In addition to stomach and rectal feeding, the subcutaneous use of sterilized olive oil and 10% glucose solution has been recommended. It would seem best to reserve the use of oil and sugar for exceptional cases of very marked cachexia or malnutrition. It must be remembered that the sugar is slowly, and the oil very slowly, absorbed, so that effects from such feeding must not be expected for several days. In cases of marked gastric stasis, which have not been treated, improvement may be fairly rapid, both in anemia and nutrition. The weight gained, however, may be rapidly lost, and operation should be done at the first step backwards. In general, as I have said, too much reliance should not be placed on attempts to build up patients by nutritives.

In cases of gastric stasis, the amount of urine is apt to be small. For two or three days previous to operation, the patient should always have sufficient liquids, either by subcutaneous infusion, or large saline enemata.

(2) As a result of Harvey Cushing's work on the "Bacteriology of the Upper Intestinal Tract," published in Welch's *Festschrift*, attempts have been made to render the part to be operated upon as free as possible from bacteria. In a considerable number of cases, the contents of the stomach and upper intestine have been proved to be sterile, as the result of the following treatment:

Thorough gastric lavage, once or twice daily, until the fluid returns clean, careful attention to carious teeth and suppurating gums, with the frequent use of antiseptic mouth washes. Free catharsis by salines, in those cases in which the condition of the patient does not contra-indicate it, and the administration of nothing but sterilized food and boiled water by mouth. The value of gastric lavage, and cleanliness of the mouth, will be granted by all, and few will object to saline cathartics. But the value of sterilizing food is open to some question, as it must pass through a cavity necessarily unclean. Egg white, soups, tea, alcohol, are probably relatively free from germs, and the value of careful sterilization is somewhat doubtful. Whatever the judgment of the surgeon may dictate about the amount of such preliminary treatment, it is always of advantage to give nothing but easily digested, soluble food, for thirty-six to twenty-four hours previous to operation. The stomach should at least be thoroughly emptied and washed out on the evening before operation after which no food should be given. The operation should be done in the morning.

Depending upon the condition of the patient, and the difficulty of using the stomach tube, a washing previous to operation may be used in those cases in which there is evidence of distention of the stomach. A previous cocainization of the pharynx, with 4% cocaine, part of which may be swallowed, allows easier passage of the tube. Five minutes should be given, however, for the cocaine to act to best advantage. Two hours before operation a nutritive enema, with salt solution, up to a pint, should be given.

It is difficult to estimate the value and possible dangers of washing out the stomach after anesthesia has been induced. In some cases this procedure acts well, in others it has seemed to me that the gastric contents passed up the esophagus, and that the danger of inhalation was increased by the anesthesia and the obvious derangement of deglutition from the presence of the tube. If used, the tube should have a large caliber.

(3) Avoidance of shock. There is probably no poorer subject for operation than a case of advanced cancer of the stomach, with co-existing obstruction, starvation and anemia. Careful attention to prophylaxis against shock will here be well rewarded. The room should be warm, 72 to 75°, the patient should be completely enveloped in a flannel suit and well-covered with blankets, about which hot water bottles should be placed. Anesthesia should always be as light as is

[1] The following papers on the general subject of gastro-enterostomy were read at the Surgical Section, Suffolk District Medical Society, Feb. 3, 1904.

compatible with the avoidance of vomiting and the relaxation of muscles. The abdomen should be prepared before the anesthesia is started, and covered with sterile towels. The operation should be begun immediately after the patient is anesthetized, and continued uninterruptedly until completion. No delay which can be avoided is admissible. Rapid though careful operation has much to do with ultimate success. Morphia and atropine given one-half hour before operation often cause a quieter anesthesia.

REMARKS ON EXPLORATORY LAPAROTOMY IN CACHECTIC SUBJECTS.

BY DANIEL FISKE JONES, M.D., BOSTON,
Surgeon to Out-Patients, Massachusetts General Hospital.

THERE is little to say about "the technique of exploratory operations in cachectic subjects," except to emphasize a few well-known facts. Some here would undoubtedly say that there was nothing to say, as such patients should not be operated upon, but that some of these patients deserve an exploratory laparotomy many will admit. Those who oppose exploratory measures usually overestimate the suffering, and especially the mental suffering. Many of these patients are perfectly indifferent to what is done to them while some ask for an operation. That they do suffer for twelve hours cannot be denied, but after that the pain is often less than before operation. In a recent case the patient said he would be all right if he could only be relieved of his pain. After an exploratory laparotomy his pain almost entirely disappeared and when seen a month after leaving the hospital, his only complaint was that he was very weak. In another recent case of cancer of the cardiac end of the stomach the pain was much lessened after an exploratory laparotomy, and the patient gained five pounds in six weeks. This was undoubtedly due in great measure to the careful supervision of diet after operation by Dr. Joslin.

Looking at these cases from a purely humanitarian point of view, one might say that it would be a blessing if the patient did not recover from the ether, but should we be willing to take the part of the executioner? We must start with the idea that it is just as important that these patients should live as any other class of patients.

Because of their weakened condition and lack of resistance, it is important to save time and to cause the least possible amount of shock. To begin with the anesthetic, the most satisfactory one in all cases is ether, carefully given, and in quantities sufficient only to keep the patient quiet. Given in this way and for a short time it never becomes a depressant; the surgeon, therefore, must not be deceived by the excellent condition of the patient into prolonging the operation beyond the time absolutely necessary for it.

Nitrous oxide would not keep the patient sufficiently relaxed for a long enough period in most cases. Local anesthesia leaves the patient in full possession of his senses which is inadvisable in these cases where hopeless malignant disease is usually found, because of the mental impression such discovery would make upon the patient. Although it is justifiable to use cocaine in cases where there is some hope of saving the patient's life and the condition of the patient is such that it does not warrant giving ether, it seems to me to be unjustifiable to put a patient through so much suffering in an exploratory laparotomy. For although the incision may be made down to the parietal peritoneum with little pain, it is impossible to open the abdomen and explore it with the finger without excruciating pain. If the patient is not sufficiently strong to stand ether narcosis the operation should not be done.

The incision should be in the median line, unless there are very definite reasons for going to one side or the other, because there is less bleeding, an important factor in saving time. Abdominal surgery has gone beyond the use of the director in such incisions, and the time required now to open the abdomen should be seconds rather than minutes. An incision of from two to two and a half inches is usually sufficient; the size is important because of the length of time required to close the larger incisions.

Before exploring the abdomen, the surgeon must have it definitely in mind as to what is operable and what is not.

Mayo-Robson gives the following conditions as inoperable:

(*a*) Cases in which extensive and extremely dense adhesions to the liver, pancreas, gall bladder, etc., are present.

(*c*) Cases in which a widespread enlargement of lymphatic glands is found.

(*c*) Cases in which secondary deposits in the liver or elsewhere are seen.

Although Mayo-Robson does not consider mural carcinoma of considerable extent inoperable, it must be to the great majority of surgeons in cachectic subjects. Von Mikulicz hopes that cancer of the cardiac orifice may come within the safe reach of capable surgeons, a hope which has not yet been realized.

The surgeon should know his own ability and limitations, and should estimate the power of the patient to withstand an operation before he opens the abdomen, that there may be no delay then. To shorten the operation and avoid shock as much as possible the surgeon should be the only one to examine the abdomen and the sole judge as to the advisability of proceeding.

If one expects to make a positive diagnosis in every case after opening the abdomen he will be disappointed, for it is impossible in many cases. I have recently seen an autopsy where a hard mass was found at the pylorus. The pathologist was unable to make a diagnosis even when the mass was removed and put before him. If this is true how can a surgeon expect always to make a correct diagnosis on the living.

Enlarged lymphatic glands are not safe specimens to remove for examination, as they may be simply inflamed and not infiltrated with new growth.

Enthusiasm for pathological specimens should be restrained in all cases where the diagnosis can be made with any degree of certainty, or where the condition is evidently inoperable, for removal of sections complicates an exploratory laparotomy tremendously in weak subjects. It prolongs the operation very materially and in some cases the hemorrhage following is a dangerous complication. The use of gauze for the purpose of walling off should be avoided if possible, for its use increases shock and makes convalescence more painful.

The method of suturing the wound is important in these cases for the patient should be gotten up early. The most rapid method is the simple through and through suture with silkworm gut. A safer method is to place the silkworm gut sutures and then put in a row of interrupted silk sutures including the sheath of the rectus, the rectus, and peritoneum, after which the silkworm gut sutures are tied. This makes a strong wound with all layers held firmly together, a very important point in cases where the patient gets up early.

If one would improve his statistics, five or ten minutes must not be wasted in preparation after the
